be removed, which the natural efforts, if unassisted, are unable to expel, adequate means must be employed, and evidences of effective operation required; but in restoring the weakened secretory organs to more healthy actions, perhaps the gentle agency of the *mistura cardiaca* may accomplish what more distinguished tonics fail to effect. We have given the formula chiefly to illustrate the treatment which we recommend, without any prejudice in favour either of the ingredients or proportions. If the principle be admitted, each practitioner may employ whatever form of cordial medicine his own experience may lead him to prefer; the object of the present work being not to lay down arbitrary rules, nor prescribe specific remedies, but to guide the young practitioner by elucidating the pathology of the several diseased conditions treated of, and establishing the principles on which rational treatment should be pursued.

So prompt and effectual is the relief afforded by the foregoing treatment in common gastrodynamia, that opium and strong stimulants are never needed. It has been shewn that, as these have no effect in removing or correcting the cause of disease, they are not the appropriate means of cure; and in this respect practice and experience fully confirm what theory would dictate. Indeed, they are not only unsuited to the cure, but when exclusively relied on, they tend to aggravate the disease and render it inveterate. The pain arises from contractile efforts of muscular fibres forcibly exerted. These are excited by the morbid mucus with which the stomach is coated, and their tendency is to throw off the offending matter. To repress the effort by narcotics or overcome it by stimulants, leaving the offending cause unremoved, is not rational practice; while the effect of such remedies immediately on the discerning membrane is to confirm the morbid actions by which the secretions had become depraved, thus adding to the evil and rendering its ultimate correction only the more difficult. All this may be deficient in proof, but it accords with all that the most successful treatment of the disease teaches. When opium is trusted to for subduing the pain of gastrodynamia, we have already said, that by frequent recurrence to it, increasing doses become requisite in order to produce the desired effect. A habit is thus acquired of pernicious tendency, and under which the whole constitution is sure to decline. The extent to which opium has been administered for this purpose has been often enormous. An old and experienced physician once told us with much self-complacency, that he had just given laudanum, in full doses, quickly repeated, to the extent of two hundred and sixty drops to relieve pain of stomach; and if the remedy had been appropriate, he would have been right in disregarding quantity, the effect, not the dose, being the object most important. But denying as we do the principle, we must condemn the practice as both empirical and injudicious. Cases may, no doubt, occur of such intense suffering as to demand full doses of opium for prompt relief; but they must be

very rare, for in a wide field of hospital practice, in which gastric derangements abound, we never meet with them. Were such a case to present itself, we should have no objection to give a full dose of opium, combined with calomel and antimony; but we would as soon as possible resort to that treatment by which alone, according to our views, the disease can ever be effectually relieved.

The patients who apply to the Bath United Hospital on account of gastrodynia have some of them suffered for weeks, months, nay years. It could not be expected that all would be relieved with equal ease, and yet the difference in this respect is much less than might be imagined. Although in recent cases removal of the cause at once arrests the spasmodic efforts which occasion the pain, it does not follow that it should succeed with equal promptitude where from long continuance the spasmodic efforts have acquired the additional force of habit; and accordingly it happens that the pain sometimes lingers even after a healthy state of bowels has been re-established. This state affords opportunity for proving the relative efficacy of auxiliary remedies. Of these the most powerful of all that we have tried is the oxide of bismuth, though how it acts we are ignorant, our use of it being purely empirical. In the dose of five grains, with one of aloes, given three times a day in conjunction with the cordial mixture, it rarely fails in this stage of the disease to give relief. In some cases spirit of ammonia is a useful addition to the mixture. A combination of equal parts of the cordial mixture and camphor julap furnishes a modification which agrees with many, especially when, as occasionally happens, hypochondriacal depression attends. Blisters to the scrobiculus often render essential aid in protracted cases. In obstinate cases we have often given purges of oleum terebinthinæ, either alone or combined with oleum ricini, and with sensible advantage, being led so to employ it from having witnessed its efficacy in improving the stomach where tenia had been suspected, but where no worm was found. A remedy of this kind, however, is rarely needed. All that has yet been said applies solely to simple gastrodynia, and for its full and effectual relief we believe the treatment enjoined to be amply sufficient. If the principles, however, which we advocate be confirmed by more extended experience, individual practitioners may modify the treatment, both direct and accessory, in whatever way their judgments may direct.

It is not our province to discuss here the more formidable maladies of which pain of stomach is but a symptom, such as scirrhus, cancer, ulceration, &c. One contingent ailment only, connected occasionally with gastrodynia, shall we here notice. Simple gastrodynia is a chronic disease, being unattended with fever or acute symptoms of any kind. Occasionally, although spasmodic pain of stomach be the chief complaint expressed, acute symptoms are seen to attend. The pulse is quick, the tongue is white, the heat of the skin is

greater than natural, and there is pain on pressure at the scrobiculus. These symptoms mark inflammatory action, which calls for its proper treatment. Venesection may here be needed; cupping or leeches over the stomach are always proper; blisters, too, may be required. The purgative formerly recommended may here seem unsuitable, yet we have not experienced any objection to its use. Should it cause pain or increase irritation, a milder should of course be substituted. If inflammation be very acute, the proper treatment of gastritis should be employed, and perfect abstinence may be advisable; but this activity of disease we have not witnessed, as contingent to gastrodynia. While inflammatory symptoms continue, it is advisable to forego the *mistura cardiaca* for one more cooling and febrifuge. Any form of antimonial saline may answer, or, what is still better if the bowels be tardy, a solution of epsom-salt in rose infusion, which will often lie on the stomach, even when simple diluents are rejected. When the inflammatory symptoms subside, the cordial mixture may be renewed with advantage. And here it may not be amiss to inquire how it is that cordial remedies are at all applicable under such circumstances, when every degree of excitement would appear incompatible. The fact that they are borne, and with advantage, is too well established to be set aside or referred to misconception, and in the researches of pathological anatomy a rational exposition may perhaps be found. Andral, in pointing out the lesions of the gastro-intestinal mucous membrane, having shewn that hyperæmia of it may be divided into three heads, as it is situated in the capillaries particularly, in both capillaries and larger vessels, or in the larger vessels only, thus proceeds: "Of these three kinds, the first belongs almost exclusively to a state of irritation, and is an almost certain proof of its existence; the second belongs equally to a state of irritation and to a state of congestion, from a mechanical cause that has acted during life or after death; the third but rarely depends on the last cause, but yet neither does it announce a state of irritation similar to that which produces a hyperæmia of the capillaries only. In fact, when the congestion is thus confined to some of the tolerably large vessels that are distributed under the gastro-intestinal mucous membrane, we have reason to think it belongs to a state of irritation that is on the decline, and we may even admit that in such cases all irritative process has completely disappeared, and that the blood, which is still accumulated in some vessels, appears there only because these vessels, having been distended by the unusual quantity of blood that traversed them as long as the irritation continued, remain passively dilated after all irritation has disappeared. This is what often takes place in the mucous membrane of the eye, in which long after the capillaries of the conjunctiva have ceased to admit blood, some larger red vessels still continue to appear on that membrane. It there frequently happens that by applying sub-

stances of a more or less stimulant nature to the conjunctiva, these vessels are forced to resume their natural dimensions, and to get rid of the blood which constantly tends to dilate them. *May not this help to account for the success which sometimes attends a tonic mode of treatment when employed towards the end of certain kinds of irritation of the alimentary canal?*" The quotation is so apposite to the subject under discussion, that, however long, we can need no excuse for thus introducing it.

It may, perhaps, be surmised that we ought to have adduced authorities in support of the opinions which we advance; but, in truth, we know not where any exist that would have suited our purpose, which, as being that of the work for which we write, is to furnish a safe and rational guide to the inexperienced practitioner. To glean from all who have treated of stomach complaints would swell this article to a cumbrous extent, and be, as we conceive, unprofitable. What we have stated, we faithfully believe to be true; and as the views which we here present are not to be found in practical works, even the most modern, we conceive that we best discharge the duty allotted us by giving them as our own judgment and experience dictate, without diverging into controversial comments, or the equally unsatisfactory practice of advancing what we could not vouch for as true.

Dr. Cullen, in discussing dyspepsia, dismisses the treatment of gastrodynia in a single sentence, merely stating that it may be sometimes relieved by carminatives, but most certainly by opiates. Dr. Darwin, while he distinguishes cardialgia as a specific disease, assigns no place in his nosological arrangement to gastrodynia. Dr. Mason Good, too, our latest projector of a methodic nosology, has seen reason for separating cardialgia from dyspepsia, and considering it a distinct disease, but he has not so distinguished gastrodynia. Dr. Heberden, the most purely practical of modern authors, attempts no pathology of the disease. He recites various influences by which it is affected, but concludes with saying, "*modo profuerunt, modo nocuerunt, et interdum fuerunt supervacua.*" For simple gastrodynia he recommends Bath waters, bitter and aromatic powders or infusions, with rhubarb or aloe to move the bowels, and some aromatic tincture to be taken after dinner. In fine, Dr. Abercrombie, the latest and best of our practical writers on gastric complaints, in his valuable *Researches on Diseases of the Stomach*, &c. takes due notice of gastrodynia, and points out some important differences in the forms which it assumes, with conjectures on their respective nature. Still not having facts on which to found a rational pathology, he attempts none; and with regard to practice his words are, "It is difficult to say what remedies are best adapted to each of these forms of gastrodynia." As the result of his own experience, he recommends sulphate of iron, combined with aloe and aromatic powder, oxide of bismuth and rhubarb, lime-water and small doses

of opiates, and in obstinate cases, bleeding, blistering, and farinaceous diet. It thus appears that the subject of gastrodynia required further investigation, and that a more discriminating practice in the treatment of it was greatly needed. How far the present essay contributes to supply the want, time and the experience of others must determine. We can only say that we have not presumed to put forward crude speculations or mere conjectures, but solely what we regard as practical truths. Sixteen years ago we published in the *Edinburgh Medical and Surgical Journal* similar views of this disease, in an essay entitled *Pathological and Practical Observations*; and in the interval which has since elapsed, we have seen nothing to alter materially the opinions then expressed; their truth being, to our conviction at least, fully proved by the uniform experience of an extensive hospital practice, in which gastric derangements particularly prevail.

(E. Barlow.)

GASTRO-ENTERITIS.—In the articles **ENTERITIS** and **GASTRITIS**, we have given a succinct description of the effects of inflammatory disease on the different portions of the digestive tube, and of the consequences of this disease on the functions of the system generally. We have also endeavoured to shew that the coexistence of inflammation in the stomach and in the remainder of the tube is not so universal as to form a law in pathology; so that, in the actual state of medicine, the following proposition of Broussais cannot be adopted:—"L'inflammation de la membrane interne ou muqueuse de l'estomac s'appelle *gastrite*; mais elle n'est jamais vérifiée sur le cadavre qu'avec celle de la muqueuse des intestins grêles. Il faut donc mieux lui donner le nom de *gastro-entérite*."*

Yet it is true that in most of the cases where inflammation either in its primary or secondary form is met with in the digestive tube, it occurs both in the stomach and in some part of the intestines. This we have verified by numerous observations, and it is more particularly to be observed in the diseases of the gastro-intestinal tube which occur in fever, and in many other cases where a typhoid state exists.

It is a fact, and we state it with regret, that the pathology of the digestive system is far from being generally understood in these countries. In consequence of this, a mode of practice disgraceful to science, and productive of the most extensive injury to human life, has been too generally adopted. In many instances,—indeed as a matter of daily, hourly occurrence,—practitioners appear to forget the existence of such an organ as the gastro-intestinal mucous membrane; and many a life is in consequence sacrificed to empiricism, to wilful prejudice, or to ignorance. Several causes have concurred to produce this state of things. Of these we may mention the following as principal:—the excessive importance which has

* Broussais, *Commentaires des Propositions de Pathologie*, cxxx.

been long attached to alterations of the liver; the spread of the doctrines of Hamilton, so popular to many minds from this, that under the name of science was put forward an empiricism easy in its application though destructive in its results, and saving the trouble of thinking and the necessity of study; the works of Abernethy, in which, though approaching to the truth, this great man did not wholly divest himself of the prejudices imbibed by early education. But we believe that there is another source, the effects of which should form a warning to all medical writers. The great facts connected with this subject, contained in the writings of Broussais, and which he was the first to proclaim to the medical world, have been received with distrust, because they were appealed to as the support of doctrines which were not found to stand the test of observation; and thus, in the rejection of the theory, have the facts been disregarded. But if the French school has gone too far, and assumed, in its generalizations, more than their facts would warrant, the British school has been culpable in rejecting those results of observation of which the ardent minds of our neighbours have made an unwarrantable use. Under such circumstances, then, how careful should a writer be; for thus not only may his own reputation suffer, but mankind be deprived, for a time, of the most valuable knowledge.

We have already alluded to the great frequency of inflammations of the digestive tube. When we take this fact into consideration, and recollect that from the singular sympathies of the digestive system a very slight disease may produce severe effects on the economy, the importance of the investigation becomes evident. Let us compare, in the latter respect, the gastrointestinal surface with the bronchial mucous membrane. In this last an extensive inflammation may exist, and yet without producing a tithe of the morbid effects on the economy which a much more circumscribed and slight gastro-enteritis will induce. In the case of serous inflammations, also, we see another example of the superiority of the sympathies of the digestive over those of the respiratory system. A pleuritis, as compared with a peritonitis, is a mild disease, and seldom fatal in its acute stage. In almost every recorded case, peritonitis from ulcerative perforation of the intestine has destroyed life with rapidity; yet in how many instances have patients lived for weeks or months with a pulmonary fistula, and consequent empyema and pneumothorax.

In the articles above referred to we have merely detailed the history and symptoms of this disease, without entering on the highly important question of its complication with other diseases, a complication already shewn to be of extraordinary frequency, and one which the study of physiology would lead us to expect. Nutrition being the fundamental function of animal life, nature has endowed its apparatus with sensibilities more delicate, and sympathies more active, than any other: hence it is scarcely possible for any morbid action of consequence to exist without its being felt in

the digestive system, where it will at first produce functional derangement, and sooner or later structural alteration. With these views let us briefly investigate the complication of gastro-enteric inflammation with disease in the nervous, respiratory, and circulatory apparatuses.

I. Diseases of the brain, both acute and chronic, are commonly complicated with gastrointestinal disease, which is in many cases the point of departure of morbid action, though in some the consequence of the reflected irritation of the inflamed brain. The headach, the somnolence, which so constantly follow an error in regimen, are examples of a slight degree of irritation of the brain, induced by the sympathetic action of the digestive system,—a degree of irritation which, if more severe, or too often repeated, may come to actual inflammation. The occurrence of epilepsy or convulsions from the same cause is familiar to every practical man, and points out to the physiological observer the close connexion of the systems, and the danger of over-stimulating the digestive apparatus. These are examples of acute attacks from which the system often relieves itself without consequent injury; first, because the irritation of the digestive system is generally transient; and, secondly, because the brain is not yet disorganized. But when inflammation becomes fixed in the digestive system, either in its acute or chronic form, then we may see, in the first case, the most marked evidence of cerebral irritation; and the records of medicine abound with examples where, in the second case, the long-continued sympathetic excitement has produced or been followed by a variety of diseases of the brain, and where the original affection was unknown or mistaken, and consequently maltreated.

We are far from believing that most cases of cerebral irritation are secondary to a gastro-enteritis; but medical writings—not to mention our own observation—can be safely appealed to in support of the doctrine that a number of them are thus produced: and it is to the important consequences of this knowledge that we wish to call the attention of our readers. From ignorance of this fact, many cases of arachnitis, and especially that of children, are improperly treated; for the cure is attempted by revulsion upon the originally suffering organ. In the language of the day, the purging practice gets a "*fair trial*," and the child dies more often of the exasperated intestinal inflammation than of the disease in the brain. From this complication not being recognized, every one must have seen great errors in practice. More than once, in cases where convulsions had supervened on symptoms of gastric disease, we have seen the cure attempted by the exhibition of the most stimulating antispasmodics—a practice always improper, but in such a case mischievous in the highest degree. We recollect more than one instance in which eminent practitioners prescribed for this disease a combination of ether, ammonia, tincture of assa-fetida, camphor and opium, where every dose produced a convulsion. In one of these cases

life was apparently saved by a timely inhibition of the antispasmodics, and the substitution of drinks of cold water, (the best medicine in such a case,) and the use of leeches to the head and epigastrium.

We have already given examples of the effect of gastro-intestinal inflammation in inducing irritations of the brain and spinal marrow in the adult, and have alluded to the remarkable fact, that where the sympathetic excitement of the nervous system is severe, many of the proper symptoms of the original disease are absent. This fact, observed by Hippocrates, is one of great practical importance, as it teaches us that in such cases the most violent disease may exist in the digestive system without pain, and often without other symptoms commonly observed in the uncomplicated disease. On this subject Lallemand makes the following excellent remarks:—"It is not because the pain of the head is more severe than that of the abdomen, &c. that this disappears, for there is frequently no headach; it is not because the inflammation is more violent, since a serous or sanguineous effusion will produce the same result; but it results from this, that pain being the result of a sensation perceived by the brain, whatever alters its functions removes this symptom of the inflammation. But if this inflammation be intense, it is not influenced in its development by the cerebral affection, and all its other phenomena continue, because, unlike the sensibility, they are not under the dominion of the brain: *the disease runs its course in a more dangerous manner, because it is more difficult to recognize, and causes death, which is attributed to the cerebral affection, although this is but a secondary disease.* On dissection, we are often surprised to find so little relation between the symptoms (cerebral) and morbid alterations."^{*}

The supervention of fever in the course of softening of the brain is generally owing to some inflammatory affection of other organs. The seat of this is so frequently in the digestive system, that in such cases the mere occurrence of fever should lead us to investigate narrowly the state of the digestive tube. All the cases where fever occurred, as recorded by Lallemand, presented this complication, although in most of them the belly was soft and free from pain. The importance of these facts in the treatment of cerebral disease must be evident to every unprejudiced mind, more particularly when the revulsive treatment is considered. How constantly is the emetic and purgative plan used for the relief of cerebral diseases; and yet there are abundant facts to prove that such treatment, as a general rule, is always hazardous, and often the immediate cause of death. The writings of Desault have been one cause of this prejudice in favour of the revulsive treatment, as directed on the digestive system; but how few follow exactly the mode which he has laid down. Practitioners seem to forget that it is clearly illogical to

conclude, as so many have done, that, because a moderate revulsive treatment is useful in injuries of the head, the same is equally applicable to idiopathic encephalitis: the cases are essentially different. Morel, in his translation of the work of Richter on wounds of the head, states that the experience of five years, during which he was a pupil of Desault, has taught him that the success of the tartrate of antimony in injuries of the head was never attributable to the vomiting which it might produce, but that, on the contrary, this result always exasperated the disease. Lallemand declares that tartar emetic is a most hazardous remedy in cases of cerebritis, as, whether it produces vomiting or is retained, it may be injurious; in the one case apparently from the mere act of vomiting, in the other by inducing a gastro-intestinal inflammation.

With respect to purgatives, we are far from wishing to inhibit their employment in cases of disease of the brain, as there are unquestionable instances of their utility; but we protest against their empirical employment, and insist on the necessity of carefully investigating the state of the mucous membrane, and of bearing the facts which have been detailed in mind, before we attempt anything that may compromise the integrity of so important an organ.

In the treatment of delirium tremens we have often witnessed the worst effects from overlooking the state of the stomach. Although we do not believe, with Broussais, that this affection is merely the result of the sympathetic irritation of the brain from an inflamed stomach, yet we feel satisfied that in those cases where the disease has supervened on a debauch, there is more or less of gastric inflammation. From not recollecting that most important law in pathology, that similar symptoms may be induced by opposite states of an organ, a grievous error is commonly committed in the treatment of delirium tremens. For example, a person who has been in the daily habit of drinking spirits meets with an accident; he is placed in an hospital and debarred from his usual indulgence; symptoms of delirium tremens supervene, *which are found to subside on the stimulus being resumed.* From this fact has arisen the practice of giving stimulants in the disease occurring after a debauch, but it requires little acumen to see that these are two essentially different cases. We have often witnessed the result of this unphilosophical treatment: the symptoms of delirium tremens are converted into those of encephalitis, and a violent gastritis or gastro-enteritis is induced.

In the case of debauch the stomach has been over-excited, and is probably inflamed; another organ is suffering, and of course many of the proper symptoms of gastritis will be wanting: but even where there was no indication of gastritis but thirst and epigastric tenderness, we have seen the most striking effect on the nervous symptoms produced by leeching the epigastrium: we have seen it remove the tremor, the giddiness, and the want of sleep.

II. Let us next examine the coincidence of

* Lallemand, *Lettres sur l'Encephale*, 2.

gastro-enteric with pulmonary inflammation. An extensive hospital experience has proved to us that this is a most frequent occurrence, and one of vast importance in the treatment of disease. There is a circumstance connected with this complication which is often a source of its diagnosis, namely, *that it frequently gives to the disease a typhoid character*. We say frequently, because we have seen the combination to exist without typhoid symptoms, and because we have known simple pulmonary inflammation to cause these; but these cases seem to be exceptions to the general rule.

This combination of gastro-intestinal with pulmonary inflammation takes place equally in affections of the mucous membrane, of the parenchyma, and serous investment. It is also an almost constant attendant on phthisis, in which its supervention exercises a remarkable influence on the progress and curability of the disease.

One of the most frequent forms of disease in Dublin is that which may be termed the gastro-catarhal fever. It is a disease in which there is an inflammation both of the pulmonary and gastro-intestinal mucous membranes. It is one of great danger, and from the following circumstances:—1. the existence of an intense gastro-enteritis; 2. the fact that the bronchitis is almost always double and universal; 3. that at the time when the bronchitis is passing into the second or secretive stage, there is generally profound debility, so constant in gastro-intestinal disease: expectoration cannot take place, and the patient dies of asphyxia. These are sufficient to prove the danger of this disease; and we may add that, as in the complication with cerebral disease, the gastro-enteritis in this instance is *constantly observed without pain, tenderness, or vomiting*.

In such cases it would appear that the mucous inflammation is in some instances the cause, in others the consequence of the fever; but whether it be cause or effect, it is to its reduction that the efforts of the physician are to be mainly directed. How important, then, must be the recognition of the gastro-enteritis. Independent of any theory, an extensive experience has led us to conclude that in these cases all practice tending to relieve the chest by revulsion to the gastro-intestinal surface, whether by nauseating or purgative medicine, is improper. The chest will not be relieved, and the gastro-enteritis will invariably be aggravated. The true principle of treatment is to deplete both the respiratory and digestive systems, and this is to be effected chiefly by local bleeding and counter-irritation. We say local bleeding; for in many of these cases general bleeding is inefficacious and sometimes injurious. This result appears due to the gastro-intestinal complication; for in simple bronchitis the lancet is constantly of the greatest utility.

There is a remarkable fact connected with this disease, to which we have alluded in the article ENTERITIS,—namely, that the inflammatory action seldom possesses the same degree of intensity in both systems at once:

we observe a species of alternation of intensity. Thus, when the swelling and tenderness of the belly, the diarrhoea, the redness of the tongue, and the typhoid symptoms are best marked, we find the face least livid, the breathing and cough easier, and the stethoscopic signs of disease by no means so evident. But in the progress of the same case the gastric affection will appear to subside, to be replaced by all the signs of an intense bronchial inflammation. In the course of a gastro-catarhal fever this change of symptoms may occur several times. The knowledge of this is of practical importance, for the apparent diminution of the symptoms of gastro-enteritis does not imply that the parts have become healthy; and if we practise on this supposition, we may be sure that the abdominal disease will reappear with violence. This we have seen to occur from a dose of tartar emetic, or a purgative pill. In some cases where the patients have died during the exacerbation of the bronchitis, we have found numerous intestinal ulcerations, although the surrounding mucous membrane was pale. (See ENTERITIS.)

The practical conclusions which the knowledge of the gastro-intestinal complication leads us to, appear to be the following:—

1. That, as a general rule, the lancet is to be used with much more caution in this complication than in simple bronchitis.

2. That we are to place our chief reliance on local bleeding and counter-irritation, on both the chest and abdomen.

3. That the emetic and purgative treatment is in these cases highly dangerous.

4. That the combination of mercury with opium exhibited so as to induce ptyalism, appears to be the remedy most entitled to confidence, after local bleeding and the use of blisters.

5. That the apparent subsidence of one class of symptoms does not imply that the disease from which they arose has subsided.

6. That in the convalescence of these patients peculiar attention must be paid to the state of the gastro-intestinal tube, as a slight error in diet or an over-dose of laxative or purgative medicine may be productive of the worst results.

The existence of a bronchitis is much less likely to induce a gastro-enteritis than the latter to induce the former. This, however, is only one of the exemplifications of the fact that the digestive system is endowed with more powerful sympathies than any other. Facts are still wanting on the subject of thoracic disease supervening on abdominal, but every observer must admit its frequency. We have thus a key to the explanation of the tussis verminosa, the tussis hepatica, the dyspeptic phthisis, &c. A circumstance of not uncommon occurrence well illustrates the danger of the empirical treatment of gastro-enteric inflammation. When the disease predominates in the lower part of the tube, diarrhoea, as formerly stated, is a common symptom, either as occurring from acute or chronic enteritis. Nothing is more common than the treatment

of this by astringents, or by stimulants, such as the turpentine. Now we have frequently observed that, where the secretion was thus arrested, the diseased action appeared to be immediately translated to the bronchial surface, and these cases are always of the worst description. All the results of inflammatory action on the lung may be thus produced, yet the evil is seldom attributed to its proper source. The best mode of avoiding this accident in cases where we are forced to resort to the astringent and stimulating treatment of diarrhoea, is at the same time to determine to the skin; and the means which have succeeded best in our hands are the warm bath, counter-irritation on the abdomen, and the use of flannel next the skin. We should also in the treatment of such a case diligently watch the state of the respiratory function, and on the first appearance of disease, as shewn either by symptoms or the stethoscopic signs, immediately omit the remedies calculated to arrest the abdominal secretion.

Of the combination of pneumonia with disease in the digestive tube, we have witnessed a vast number of cases, and it appears highly probable that the disease termed by the older authors the *putrid pneumonia*, *pneumonia typhodes*, &c. is an example of this combination. About two years ago, so many cases of this disease were admitted into the Meath Hospital that it might be considered as epidemic in Dublin. The patients generally presented the following symptoms. There was great prostration, often much more than could be accounted for by the extent of the pulmonary affection as observed by the stethoscope. The skin was generally cool and clammy, and frequently covered with small livid petechiæ; the pulse small and feeble, and the countenance collapsed and anxious. But little pulmonary oppression was complained of; there was cough, and in some cases the rusty sputa occurred, while in others nothing but a little colourless mucus was expectorated. The detraction of a few ounces of blood almost invariably produced syncope, and did not afford any relief to the patient. In a few cases the blood presented the inflammatory crust, but in the great majority this appearance was absent. In addition to these symptoms we remarked a red and crusted tongue, and, frequently, sordes on the teeth; there was thirst, some swelling of the belly, which was tender, particularly in the epigastric and right iliac regions, and often diarrhoea. The intellect was obtuse, and occasionally a low delirium supervened. On examination by the stethoscope and percussion, the usual signs of the different stages of pneumonia were observed, and in several cases the disease, contrary to its usual course, occupied the superior portions of the lung.

This was an extremely dangerous and unmanageable disease; many of the cases proved fatal, and in those where the disease was arrested, the convalescence was very tedious and doubtful. The pulmonary congestion resolved with great slowness; and where hepatization had occurred, the dulness on percussion con-

tinued for a great length of time. The patients remained in a semi-hectic state, and nutrition went on slowly. In the fatal cases death appeared to be induced much more by the abdominal than the thoracic disease, which was seldom so extensive as to account for the fatal termination. On dissection, the various appearances of the different stages of pneumonia were found. The stomach was generally more or less vascular and softened; but it was in the lower third of the ileum that the greatest destruction was found. Here the mucous membrane was intensely injected and of a purplish red colour. The glands of Peyer and Brunner had become extensively ulcerated, and in some cases suppuration of the mesenteric glands was observed to a great extent. The blood was fluid and dark-coloured, and the peritoneum had a livid hue.

If we compare the description given of the *nervous peripneumony* by P. Frank, we must observe a striking resemblance between it and the disease under consideration. In both we have the pulmonary inflammation conjoined with a group of typhoid symptoms. He also speaks of an epidemic pneumonia combined with gastric symptoms, and in both cases points out the inability of the patient to bear free bloodletting. From the light which the study of the phenomena of gastro-enteritis has thrown upon the nature of typhoid inflammations, there can be little doubt that in these cases much of the typhoid character is owing to the abdominal complication, and we may consider the nervous and putrid pneumonia of the older writers as of this nature.

But does the mere existence of this gastro-enteric inflammation necessarily produce a typhoid state in cases of pulmonary disease? or are both the pulmonary and gastric symptoms the result of the secondary inflammations so constant in fever? We incline strongly to the latter opinion, as we have seen an intense enteritis with pneumonia where the typhoid symptoms were absent, and where the patient bore large bleedings well. But in a practical point of view, this question is not of great importance; because, whether the gastro-enteritis be the primary affection, or secondary to the typhoid state, its existence is of the greatest importance in the prognosis and treatment of the case. This we have mentioned in the article GASTRITIS, where it is stated that the tartar-emetic treatment of pneumonia, as recommended by Laennec, is full of danger in these cases. The opinion of this author, that a gastro-intestinal complication does not contra-indicate the use of tartar-emetic in large doses, in cases of pneumonia, is one of the few errors in the work of that great man,—an error which it is much to be feared he was led into by his too great prejudice against the doctrines of the physiological school.

We have not observed in this disease, as in the gastro-catarrhal fever, those remarkable alternations of symptoms between the chest and abdomen; the character of the disease being seldom changed throughout its course.

The practical conclusions which the knowledge of this complication of pneumonia leads to are the same as indicated when speaking of the gastro-catarhal fever. In this disease the strength of the patient must be supported by farinaceous foods, jellies, and chicken-broth, from an early period, even while we are using local bleeding to the chest or abdomen. The best internal remedy seems to be the combination of calomel with Dover's powder, given with a view to induce pytalism. This should be assisted by mercurial frictions. As soon as the gums are decidedly affected, the inflammatory action often begins to subside. At this period we have also found the greatest advantage from the use of the polygala senega, exhibited in the following manner:

R Decoct. polygalæ senegæ, ℥vii.

Tinct. scillæ marit. 3ii.

Tinct. opii camphorat. 3vi.

Carbonat. ammoniæ, gr. xv.—℥i. M.

capiat coch. ampl. i. secundis horis.

If this remedy be given before pytalism is induced, it will not be found beneficial; but after this effect has occurred, it will seldom disappoint the practitioner. This will be generally the time to administer small quantities of wine, regulating its use by the effect on the pulse and fever. When, after the use of wine, the frequency of the pulse is diminished, and its fulness increased, we may be sure that the remedy was indicated.

We must never forget that for the successful treatment of the case, both during its acute stage and convalescence, *the double seat of the inflammation must be constantly kept in view.*

The occurrence of inflammation of some part of the digestive tube in cases of phthisis is a circumstance of extreme frequency in this disease, and one that exercises a powerful influence on its progress and the chance of recovery. It most usually presents itself under the symptoms of what is called the phthisical diarrhoea, but has been observed in a much more acute form.

As in cases of idiopathic gastro-enteritis, and in that supervening in fever, so in this disease we may meet with the inflammation in some cases predominating in the upper, in others in the lower part of the tube. The lesions of the mucous membrane of the stomach are indicated by loss of appetite, nausea, bilious vomiting, and epigastric pain; the tongue may or may not be indicative of the gastric disease. These symptoms we regret to say are generally disregarded in cases of phthisis, and in numerous instances we have seen the worst consequences from this oversight. The vomiting in particular is attributed to the effect of coughing, as in pertussis, and there is no doubt but that it may be thus induced; but in those cases, as Louis has remarked, the appetite is good, the digestion easy, and the epigastric pain is wanting. It is further to be recollected that vomiting independent of disease of the stomach most commonly occurs in the early periods of the case; but that in the more advanced stages it is almost always the result of gastric inflammation. On this subject, however, it would

not be right to omit the following remark of Louis:—"Nevertheless, in this instance, as in a thousand other circumstances, there are facts which defy the sagacity of the observer, and form exceptions to the most general laws. Thus in the last months of his existence, one of our patients had epigastric pains, nausea and vomiting, both during the cough and its intervals, although the mucous membrane of the stomach was perfectly healthy.*"

As an encouragement to our paying particular attention to the state of the stomach, it may be mentioned that there are facts on record which prove that, even in phthisis, an ulcer of the stomach may become cicatrized. The gastritis in this disease is almost always secondary to the tuberculization of the lung; but by interrupting nutrition, and by the prostration of strength which it induces, it exercises a most fatal influence on the progress of the disease. Seldom recognised, and constantly exasperated by the introduction of stimulants under the name of tonics and expectorants, it adds incredibly to the sufferings of the patient; and where from this mistaken treatment, and from the use of stimulating diet, it becomes acute, the respiration grows hurried and laborious, and additional blisters are mercilessly laid on the patient's chest, while the source of his increased suffering is wholly overlooked.

But the most striking as well as most frequent indication of abdominal disease in phthisis, is the occurrence of diarrhoea, a symptom the nature of which is not yet sufficiently appreciated by medical men. From the fact that this symptom is occasionally suspended when the perspirations are copious, an occurrence by no means so general as has been represented in books, it is looked on as a sort of vicarious discharge, and its cause, which is an enteritis, is seldom recognized. From this error great injury constantly follows. Diarrhoea in phthisis is an almost certain indication of disease in the mucous membrane and glands of the ileum and colon; a chronic inflammation, terminating in ulceration of these tissues. In the present state of pathology, it may be laid down that diarrhoea in phthisis almost never occurs without enteritis; and further, that in this disease we may have some degree of enteritis without diarrhoea. This, however, is a rare case, and in our experience has only occurred where the colon escaped alteration. The experience of more than a hundred cases, in which we have made a post-mortem examination, has convinced us that in phthisis the diarrhoea is the result of inflammation and ulceration of the intestine,—a conclusion which we look upon to be as free from exception as any doctrine in medicine can be; but one, however, which, though not new, is far from being sufficiently recognized. It is most important to consider this secondary enteritis, in cases of phthisis, both with a view to the curability of consumption, and also to its palliative treatment. Of one fact we are convinced, namely, that the absence of enteric

* Recherches sur la Phthisie.

inflammation greatly prolongs the existence of a phthisical patient, and of course increases the chance of a cure. We know that in most cases of chronic phthisis an attempt at cure is established by nature, the mechanism of which has been developed by the immortal Laennec. For the success of this attempt two conditions appear requisite,—one, that the life of the patient shall be prolonged so as to allow time for the cicatrization of the abscess; the other, that the tuberculization of the lung shall not advance so as to produce too extensive disorganization of the part. Now the first of these is mainly influenced by the supervention of the enteritis. In all the cases of very chronic phthisis which we have observed, the intestinal disease either did not occur, or only supervened at the very close: in these cases the disease lasted for years. But we believe also from observation, that the second condition is greatly influenced by the state of the digestive system; as, after the diarrhœa has commenced, the disease, as observed by the stethoscope, has advanced with increased rapidity; a circumstance not at all strange to the pathologist, and explicable by the sympathetic irritation and lesion of nutrition.

We have now had the good fortune to witness the recovery of several patients in whom the stethoscope unequivocally indicated the existence of tuberculous cavities. *In none of these cases was there any enteric complication.* The disease advanced slowly, and time was given both for the efforts by nature, and the operation of remedial measures.

From considering phthisis in all cases merely as a pulmonary affection, and from not estimating the importance of gastro-intestinal disease as influencing its progress, a fatal error is commonly fallen into: this we have often witnessed. A young female ceases to menstruate; this may or may not have been preceded by pulmonary irritation; but in most instances some affection of the lungs is present: she gets worse, and consumption is apprehended; the symptoms are attributed to the amenorrhœa, and the cure is attempted by forcing the uterine action by the medicines called *emmenagogue*. A variety of substances, all highly stimulant to the gastro-intestinal surface, are exhibited; many of them, such as aloes, savine, &c. &c. of a drastic nature; the result of which is, that a diarrhœa is established, attributed at first to the medicines, but from its obstinacy shewing that it proceeds from a diseased state of the bowels. The phthisical symptoms advance rapidly; the menses do not reappear; and the patient dies of what is called a *galloping consumption*. We have actually known cases where the emmenagogue system was continued after the phthisical diarrhœa was established, and cavities formed in the lung. Such lamentable circumstances may well be appealed to by those who ridicule medical science; but the opprobrium ought to fall on the individual practitioners who will not stoop to learn what the science is capable of teaching.

Although so instrumental in accelerating the fatal termination of phthisis, enteritis is sel-

dom a cause of sudden death in this disease. Notwithstanding the number and extent of the ulcerations, yet perforation of the intestine and consequent peritonitis is extremely rare; a most interesting fact, and one which we have endeavoured to explain in the article *ENTERITIS*. The only case of phthisis in which we have found perforation of the intestine was an example of acute development of tubercle, accompanied with intense pulmonary irritation and obscure abdominal symptoms. On dissection, several perforations were found, but the fecal matter had not escaped into the serous cavity. The disease in the intestines was most extensive, and could never have been suspected from the symptoms;—another instance of the latency of abdominal inflammation when other disease exists. This case is published in the fifth volume of the Dublin Hospital Reports. We have witnessed one case, where sudden death occurred from hemorrhage of the bowels. The patient in an advanced stage of phthisis, while at stool, suddenly fell down dead. A large quantity of blood was discovered in the night-chair; and on dissection the colon was found extensively ulcerated and filled with blood. This termination of phthisis is, we believe, not noticed in any of the systematic works. The case will be found in the Transactions of the Association of the College of Physicians of Ireland, 1827.

In the more acute forms of phthisis, the complication with enteritis may also exist; but on this subject facts are still wanting. In some instances we have seen the disease commence with violent symptoms of bronchitis and dysentery, and pass into those of phthisis and diarrhœa. These cases were not unfrequent after the late epidemic fever in Dublin, and were observed chiefly in the convalescent patients. One case occurred during this period which is remarkable, as it presented the symptoms of an intense irritation of the gastro-intestinal mucous membrane, yet on dissection this tissue was found generally healthy. The solid viscera of the abdomen, however, were universally tuberculated, the tubercles being in great quantity and in various stages from the milinary to the crude state. The lungs were completely filled with milinary and granular tubercles, and the bronchial mucous membrane highly vascular. From the symptoms referable to the abdomen, we fully expected to find an intense gastro-enteritis; there being tenderness of the abdomen, with tumefaction, purging, the tongue dusk-coloured, great thirst, delirium, and involuntary evacuations. The only morbid appearance in the tube was a slight vascularity and softening of the ileo-cæcal portion, with some enlargement of the muciparous glands—an extent of disease quite insufficient to account for the symptoms. How far these are to be referred to the condition of the solid viscera is a subject for further investigation.

In the treatment of phthisical diarrhœa it is of consequence to bear its true pathology constantly in mind, even though we should despair of effecting a cure. The disease itself is so full of danger, and the symptom so distressing,

that its palliation is an object of great importance; and this will be best effected by acting on pathological principles. Although astringents are not unfrequently our only resource, yet their indiscriminate use is dangerous, as the checking of the secretion may be followed by increase of fever, and great aggravation of the pulmonary symptoms. This is more commonly observed in cases where the disease has not arrived at its last stages. The mind of the practitioner should be impressed with the fact that the disease is an enteritis, and to be treated as such; and we can safely assert that in hospital practice we have found the application of a blister to the abdomen seldom fail in arresting the diarrhoea, and giving the greatest relief. In this practice there is no danger, for it is not empirical; we do not arrest a secretion without removing or modifying its cause. In more than one case in which astringents and opiates had failed, this practice was followed by a permanent removal of the diarrhoea.

In our treatment of phthisis we should never lose sight of the following facts and conclusions with respect to the gastro-intestinal system:—

1. That a complication with some form of gastro-enteritis is exceedingly frequent.

2. That this complication is to be guarded against as far as possible, as its supervention exercises a fatal influence on the progress of the pulmonary disease, a result explicable by the lesion of nutrition and the sympathetic irritations.

3. That when the disease predominates in the upper portion of the tube, we have the usual symptoms of chronic gastritis super-added to those of phthisis; and when in the lower, diarrhoea is the most prominent phenomenon.

4. That where the signs of disease of the stomach exist, the diet must be of the most unstimulating kind, and that we cannot hope for benefit from tonic, stimulating, or expectorant medicines.

5. That in all stages of the disease, purgative medicine, particularly of the drastic kind, must be avoided.

6. That the diarrhoea of phthisis is the result of an enteritis with ulceration of the intestine, and that hence the indiscriminate use of astringents is as objectionable in this as in other forms of intestinal disease. (See DIARRHOEA.)

III. The limits of this article will not permit us to enter on the interesting questions of the connection between gastro-enteritis and disease in the circulatory and genito-urinary systems; but we shall say a few words on its complication with *hepatic disease*.

There is no part of the digestive apparatus to which the attention of physicians has been so long directed as the biliary system. The diseases of the liver, indeed, have been more studied than all the other lesions of the digestive apparatus; a circumstance mainly arising from the long reign of the humoral pathology, which attached such importance to the composition of the bile, and referred so

many diseases to its alterations. Much of this doctrine still remains, although modern medicine has shewn, whilst still allowing the necessary importance of the biliary apparatus, that we must consider it, both physiologically and pathologically, as secondary in importance to the gastro-intestinal surface.

The general similarity of symptoms that arise from abdominal disease tended much to retard our knowledge of the importance of diseases of the digestive tube; as in thousands of instances these were and still are described as examples of hepatitis either acute or chronic. This is an error so great, and one so universal in these countries, that it is no exaggeration to designate its consequences as dreadful.

Hepatitis in these countries is much less frequent than inflammations of the digestive tube,—a fact established by pathological anatomy, and one, the more extensive recognition of which would be fortunate for the British public. From mistaking gastro-enteritis for affections of the liver, two great evils result;—one, the neglect of the actual disease; the other, its exasperation by the means supposed capable of removing the hepatic affection. Revulsion to the mucous membrane is attempted; in other words, a tissue already in a state of inflammation and the source of the symptoms, is submitted to a double stimulation. Disorganization is thereby effected, and what was at first a simple and curable disease of the mucous membrane, becomes a chronic and incurable lesion, not only of this tissue, but of the solid viscera of the abdomen. The patient dies; and in the hepatic and splenic disease then observed, the practitioner sees a vindication of the treatment which has assisted to produce them.

The relation which exists between secreting organs and the surfaces with which they communicate, is not sufficiently recognized by practical men. It is a subject full of importance to the practice of medicine. Without denying that the glands in question may primarily contract irritation, yet Bichat has shewn that the natural mode of excitement of these organs is a stimulation exerted on the surface of relation with which they communicate; a stimulation which, in the state of health, will only induce the physiological action of the organ, but which, if excessive or too constantly repeated, will ultimately induce disease in the secreting organ itself, by the operation of one of the best established laws in physiology or pathology. We must admit that in declaring, as a general rule, that all inflammations of the liver are secondary to a gastro-enteritis, Broussais has come to a too sweeping conclusion. He deserves great credit, however, for demonstrating the frequency of the sympathetic irritation going on to true inflammation, and thereby rendering the liver itself a centre of fluxion. These remarks apply more especially to the supervention of chronic hepatitis on long-continued stimulation of the stomach and duodenum, the consequence of a life of luxury or indulgence in ardent spirits. When the liver-disease is established, it is plain that a

principal indication will be to remove or modify the original exciting cause, and to adopt such treatment as may have least chance of exasperating the diseased state of the mucous membrane.

The production of hepatitis consequent on gastro-intestinal inflammation is a subject not yet wholly cleared up. In all probability its most common cause is the sympathetic irritation, or increase of the excitement which the surface of relation naturally exercises on the secreting organ. But there are cases in which additional causes seem to have acted. Thus it is believed that in some instances, inflammation has spread by continuity of surface from the duodenum along the biliary ducts,—an opinion, however, which requires further confirmation before it can be adopted. Bouillaud and Ribes believe that in many cases the inflammation is conveyed to the liver along the internal coat of the vena portæ and its ramifications; and in the *Clinique Médicale* by Andral, two cases are recorded confirmatory of this opinion. The first is of a patient who was attacked with fever and gastro-enteric symptoms, followed by painful tension of the right hypochondrium and slight jaundice. On dissection, the stomach, lower portion of the ileum, and the cæcum were found inflamed. The liver was enlarged, very red, and much engorged with blood. It was further found that the internal surface of the inferior mesenteric veins, the trunk of the porta, and its ramifications, was intensely red, while the splenic vein and the cava appeared natural. The aorta was white; and hence it was concluded, and we think justly, that this was an example of inflammation of the abdominal veins,—a phlebitis, which being propagated to the liver, was the cause of the hepatic disease. In the second case the first symptom was a diarrhœa, followed by pains in the region of the liver, jaundice and ascites. On inspection, the liver was found in the state of red induration, and the internal surface of its veins vividly red. The same was observed in the trunk of the porta and its hepatic branches, the internal membrane of which was soft, friable, and in many places lined with an unorganized false membrane. The gastro-intestinal system presented marks of extensive chronic disease; and it is only to be added, that the general vascular system was found perfectly healthy; so that we cannot attribute the appearances in the porta to any thing but inflammation.

These cases are probably analogous to that described by Reynaud, in a patient who had experienced several attacks of jaundice, in which the right branch of the porta and the inferior cava had become obliterated. A collateral circulation was established principally by means of the external veins, not however sufficient to prevent the occurrence of dropsy.

The following conclusions seem fairly deducible from the recent researches of anatomists, with respect to the connection between gastro-intestinal and hepatic disease:—

1. That in most cases of hepatitis there is a complication with gastro-intestinal inflammation.

2. That in the majority of instances where this complication has occurred, the hepatitis has been secondary to an acute or chronic gastro-enteritis.

3. That in such cases the supervention of the hepatitis does not imply the subsidence of the gastro-intestinal disease.

4. That in the smaller number of cases the hepatic disease has preceded that of the intestine.

5. That idiopathic hepatitis may occur without any gastro-intestinal complication whatsoever. This is the rarest case.

6. That in cases where the complication does exist, we cannot always find that the intensity of the one disease is proportional to that of the other.

The influence which inflammation of the upper part of the digestive tube, particularly of the duodenum, exerts in producing hepatic disease, has been much insisted on by the physiological school. That many instances of hepatitis are thus induced, there can be no doubt; but it is true that cases have occurred where this portion of the tube was found perfectly healthy.* We formerly alluded to the production of jaundice from gastro-duodenitis, and believe that it is its most common cause. It is a curious fact, that in the yellow fever, where gastro-enteritis is so frequent, inflammation of the liver is rarely observed, although considerable alteration of the colour and consistence of this viscus is common.

IV. But we have yet to handle one of the most important parts of this subject, namely, the connection between gastro-enteritis and the phenomena of fever. Were we to enter into this at full length, we should far surpass the limits of this article; but we shall content ourselves with enquiring how far that part of the doctrine of Broussais, which refers continued fevers to a gastro-enteritis, is capable of proof. Here we wish to correct an error which is general,—namely, that Broussais attributes *all* fevers to a gastro-enteric inflammation. Such is not the fact, as all candid persons will admit who consider the two following propositions of his doctrine:—“*Les irritations intenses de tous les organes sont transmises au cœur; alors il précipite ses contractions; la circulation s'accélère, et la chaleur augmentée de la peau détermine une sensation pénible: c'est ce que l'on doit appeler la fièvre, qui est ici considérée d'une manière générale.*” (Prop. cx.) “*La fièvre n'est jamais que le résultat d'une irritation du cœur, primitive ou sympathique.*” (Prop. cxii.)†

The following is the opinion of this author on the subject of the connection of gastro-enteritis and fever. He believes that acute gastro-intestinal inflammation, when exasperated, will represent what has been called the putrid, adynamic, or typhous fever; and that in those cases where the sympathetic irritation of the brain is considerable, the disease will represent the malignant ataxic or nervous fevers.

* See the works of Louis, &c.

† Broussais, *Commentaires des Propositions de Pathologie*, 1829.

The truth of this proposition is not to be denied ; but when he declares that all the essential fevers of authors are to be referred to a simple or complicated gastro-enteritis, we believe that he has not made out his case.

It cannot be denied that this doctrine, received at first with such contempt, and scouted so generally by medical professors, especially in this country, has gained ground to a remarkable extent ; and although few, except the immediate pupils of its founder, go to the full length of his opinions, yet all who look at disease with an unprejudiced eye, and who enjoy opportunities for observation, now admit that in the production, progress, and phenomena of fevers, the digestive tube takes a most important part. In fact its pathology furnishes a key to the treatment of a vast number of cases formerly termed essential or idiopathic fevers ; a denomination, happily for mankind, now beginning to be forgotten.

Will gastro-enteritis cause the phenomena of fever ? and what will be the character of that fever ? The state of the science on this subject can be shortly expressed. Gastro-enteric inflammation may cause all the phenomena of fever. It will especially cause prostration, head-ach, delirium, subsultus, coma, thirst, anorexia, sordes, morbid tongue, tympanitis, petechiæ. All these symptoms may subside under treatment calculated to remove a gastro-enteritis, and will be exasperated by an opposite treatment. This inflammation further may present this group of symptoms without pain or tenderness of the abdomen. On this subject we shall quote from Andral :—“ Confirming by our researches the admirable observations of M. Broussais on the painless character of a great number of intestinal inflammations, we stated in 1823, that we might be exposed constantly to overlook the most intense enteritis, if we only admitted its existence in cases where pain occurred. Since the publication of these researches, numerous works published by disciples of the most different schools, have shewn that the intestines may be very profoundly affected without pain being present. We have seen this pain wanting, 1st, in cases of simple erythema of the mucous membrane ; 2nd, in those where numerous exanthematous patches covered the small intestine ; 3rd, where the large intestine was affected ; 4th, where there were ulcerations, either in the ileum, cæcum, colon, or rectum. We have found the deepest ulcerations in subjects where there was no pain ; and it is to be remarked that we only speak here of cases in which the intellect of the patients was not affected.”*

The knowledge of these most valuable facts requires to be spread much farther than has been hitherto done. Many practitioners cannot separate the ideas of pain and inflammation, and it has again and again happened to us to see the most fatal results from this scholastic error.

One of the most constant characteristics of

the fever in this disease is prostration ; and there is no local inflammation which will so peculiarly induce this state as an acute gastro-enteritis. The fever may be inflammatory or typhoid in its symptoms ; it is commonly similar to the synchus of Cullen ; it may be remittent or even intermittent. To prove every part of this proposition thousands of cases may be cited.* Gastro-enteritis may, then, occur with every form of fever ; but it may also exist without fever ; from which fact an argument may be drawn against the doctrine that the typhoid or adynamic fevers are nothing but examples of gastro-enteritis either simple or complicated. It is plain that these affections present a pretty constant and peculiar group of symptoms, and that, even supposing gastro-enteritis to exist in them all, there must be something else to give the disease its peculiar character.

Let us examine the state of the digestive tube in fevers, particularly that of the stomach and small intestines. Now there is abundance of facts to prove that when death occurs in the course of a fever, we may find the stomach healthy, and even in the cases where alterations of this viscus are found, they have no peculiar appearance so as to constitute an anatomical character ; nor, as Andral remarks, are they different from those in the bodies of others who have died of various acute and chronic diseases. We cannot then affirm that every continued or typhous fever implies the existence of a gastritis, or that this disease will cause the phenomena of fever in all instances.

But the alterations of the small intestine are much more constant, and it was from this circumstance that the doctrine of Broussais mainly arose. We apprehend that an inflammation of the mucous glands is much more frequent in Paris than in this country ; and it was natural to consider the disease in the intestines, with regard to the fever, in the same light as an inflamed state of the lung was considered with regard to the symptoms of pneumonia. Louis also, one of the most accurate and trust-worthy investigators, has declared that the inflammatory development of the mucous glands is the anatomical character of typhous fever. But even admitting that such was universally the case, still the doctrine that the symptoms of fever in these cases proceeded from this disease would not be proved, because the intestinal disease may as well be considered as secondary to the fever as the pustules of small-pox to the state of the system induced by its contagion. No one would say that the cutaneous eruption was the cause of small-pox, and we cannot help believing that the “intestinal exanthem” in many fevers is produced by a similar process, and bears a similar relation to the constitutional affection.† But whether the intestinal disease be primary or secondary, it becomes absolutely necessary, in

* See the works of Andral, Louis, Bonillaud, Bretonneau, Reederer and Wagler, Boissseau, Hewett, Bright, Abercrombie, Cheyne, &c. &c.

† See the experiments of Gaspard, Majendie, &c. Journal de Physiologie.

* Clinique Médicale.

cases where it is recognized, to direct our treatment toward its removal, and carefully to avoid every thing that can exasperate it. We believe that the disciples of Broussais may have carried the antiphlogistic plan too far in fever; but if they have killed their thousands, the followers of Brown and Hamilton* have killed their ten thousands. In the treatment of fever there are two great points for the practitioner to look to,—one, the strength of the patient; the other, the state of the viscera. In the majority of cases his practice should be to remove local inflammation, for it is of this that ninety-nine out of the hundred die; but should a case arise where, from the condition of the patient, he cannot attempt to fulfil the latter indication, let him at least not exasperate the disease.

What is the common treatment of fever? a bottle of wine on the one hand, and a bottle of purging medicine on the other; and this for all fevers and all stages of the fever! We do not wish to be understood as decrying the use of tonics or purgatives in all cases, but we do protest, in the name of common sense and humanity, against their indiscriminate employment. The experience derived from the treatment of several thousand cases of fever has convinced us of this fact, that in the treatment of this disease, particularly in its early periods, we shall be more certain of advantage from leeching the abdomen, cold drinks, and emollient enemata, than any other treatment whatsoever.

We cannot conclude this hasty review of the subject better than by the following quotation from Andral:

“Does this coincidence of lesions and symptoms suffice to shew that the *dothin-enteritis* causes the whole disease? We would willingly reply in the affirmative if we did not take the following great facts into consideration:—

“1. When, from injecting different putrid substances into the veins of an animal, we produce all the symptoms of the severe fevers of the human species, there are cases where at the same time we cause various lesions in the intestinal mucous membrane, particularly various degrees of follicular tumefaction and sometimes ulcerations. At other times in these experiments the same symptoms were produced without any trace of lesion being found in the intestine. In this second case we cannot attribute the symptoms to a lesion of the digestive tube which did not exist. In the first case it is plain that the intestinal lesion was an effect, and that it was only developed by the introduction of deleterious substances into the circulation. 2. Observations formerly cited do not permit us to doubt that in the human species symptoms completely similar to those which coincide with *dothin-enteritis*, may occur without it, and without any lesion of the digestive tube. 3. The intensity of the lesions which characterise *dothin-enteritis* is not

always in relation to the severity of the symptoms observed during life.”*

But even with the facts as stated above before us, it must be admitted, that when all those facts recorded in the present article and the two preceding so often referred to, are duly considered, the doctrines of Broussais, with respect to gastro-enteritis, are highly worthy of a careful examination, and do not deserve to be designated, as they so constantly are, as the vague fancies of a heated imagination. When we reflect on the vast influence which gastro-intestinal inflammation exerts in the phenomena of most fevers; that in many of the eruptive diseases it is present and constitutes their danger; that in the varieties of cholera it is a common occurrence; that dysentery, diarrhœa, and a host of abdominal affections are its results; and that it produces the most important modifications in all other diseases,—complications, on the recognition of which their successful treatment mainly depends;—we cannot help expressing a feeling of gratitude to the great pathologist who has awakened the attention of the world to this universal and destructive disease. It is absurd to reject facts because their discoverer may have made use of them to form a theory which the progress of science has partially disproved; and it is worse than ungenerous to deny him that civic crown which he has so truly and gloriously earned.

(William Stokes.)

GLOSSITIS, (derived from *γλῶσσα*, the tongue,) *inflammation of the tongue*. Although in strictness of language the term *glossitis* may be applied to the partial inflammations of this organ, frequently induced by the direct application of irritants, whether taken into the mouth with food or drink; of corrosive or acrid substances, or occasioned by mechanical injury, such as the forcible inclusion of the tongue between the teeth, or by friction against the ragged edges of such as may have been broken or decayed; it is nevertheless generally used to denote a specific inflammation either of the substance or coverings of the tongue, or of both, induced through the medium of the system, or sustained by a peculiar condition of the organ itself. Some diseases of the tongue, however, of which inflammation has only been one of the conditions, and others in which all the characteristics of it have not been present, have been occasionally described under this name.

The partial inflammations just noticed seldom require further therapeutic consideration than the avoidance of those causes which may renew irritation, and the removal of others that may continue to exist; the operation of nature under such circumstances being almost always sufficiently sanatory without the interference of art. It must indeed excite surprise, that an organ so constituted, so frequently exposed to the action of irritants, and so often exhibiting changes sympathetic with morbid

* We must admit that much of the abuse of purging in fever has originated in a misconception of the real doctrine of Hamilton.

* *Maladies de l'Abdomen.*

conditions of other parts of the body, should be so little prone to incur either this or any other idiopathic disease. The little liability to extension of inflammation excited by mechanical or chemical irritants is within proof of every one's experience; but in some instances in which the disposition to scirrhus has been latent, its development has soon followed the inflammation consequent to the injury;—a sufficient reason for inculcating the necessity of avoiding all causes by which it might be aggravated.

The same remarks are applicable to general inflammation of the coverings or substance of the tongue, to which some peculiar predisposing state of the organ itself, influenced probably by a particular state of the constitution, added to that of an inflammatory habit or sanguineous temperament, is conducive. Of the nature of these predisposing causes we are yet ignorant, and rather than waste time in discussing the mere conjectures which have been offered to explain them, we shall avail ourselves of the technicality of science, and include them under the term *idiosyncrasy*.

The exciting causes doubtless consist of those which are common to inflammations in general, and are such as contribute to repletion, either by food or drink; the suppression of accustomed discharges or of natural secretions, particularly of perspiration, either general or local, from exposure to cold; the immoderate use of stimulating liquors; and the direct application of corrosive or acrid substances. The same mechanical and chemical irritants which we have stated to be exciting causes of partial inflammation may also produce the general affection which it is our present design to discuss.

Idiopathic inflammation of the tongue, or glossitis, is a very rare disease, and very formidable in itself, as well as in reference to its influence on the functions of respiration and deglutition, both of which are in general materially impeded by its presence; the former so much so as to endanger life. It commences with the usual constitutional symptoms common to inflammatory diseases, accompanied with some uneasiness of deglutition; the tongue is rendered painful, and the patient sensible of its enlargement, which is evident on inspection: its surface, at first very red, soon becomes coated, except at the tip and lateral margins, with viscid whitish mucus; the articulation is indistinct, and any attempt to move the organ, or pressure upon it, increases pain: the saliva appears to be profusely secreted, but the inability and disinclination of the patient to remove it from the mouth accounts, in a great measure, for the accumulation and dribbling which are always going on. The local pain increases with the progress of the swelling, which is very rapid; speech and the natural motions of the tongue are consequently more and more difficultly performed; and the augmented bulk, encroaching posteriorly on the space assigned to the passage of air and nutriment, increases the difficulties of respiration and deglutition. The pressure also is a source of irritation to the larynx, and occasions a cough, which under the

circumstances of the disease is peculiarly harassing; and the cavity of the mouth being too small to contain the tongue in its increased volume, the organ is consequently protruded. In this state it is obvious that a mechanical impediment must exist to the free course of the blood to and from the head; and from this cause there takes place a throbbing of the arteries, an undulatory motion in the jugular veins, lividity of the complexion, an unnatural prominence of the eyeballs, altogether occasioning an appearance of fulness of the face similar to that consequent to strangulation from any other cause: the accompanying sensations are pain of head, and generally in the ears, vertigo, sometimes indistinct vision, and confusion of mind, or even delirium; considerable pain is also often experienced in the tract of the spinal cord and parts adjacent, from the cervix downwards.

The constitutional or febrile symptoms are influenced by the local affection: the pulse is frequent, full, and hard, but smaller as the disease advances, and as the impediment to respiration becomes greater; the skin, which in the early stage is dry and burning, at length is bedewed with accessions of cold perspiration; there is excessive thirst, the bowels are confined, the urine is red, sparingly secreted, and deposits the lateritious sediment. The patient in this state can rarely sleep, and the irritability of the nervous system rapidly leads to an alarming degree of exhaustion. It occasionally happens that the inflammation is confined to one half of the tongue, the raphe being the line of demarcation between it and the unaffected side. In such cases the constitutional as well as local symptoms are materially modified; so also are they by a variety of other circumstances, such as the extent of the inflammation, the age and temperament of the individual, and the habit of body which may have immediately preceded the accession of the disease.

The progress of glossitis is like that of other inflammations, and terminates either in resolution, suppuration, gangrene, and change of structure, or conversion into other disease. When the inflammation of the mucous membrane of the tongue has been excessive, the lymph effused has been formed into a distinct expansion, like that which usually is found to take place in *cynanche trachealis*; and as the tendency is probably always the same, the occurrence, we conceive, would be more frequent but for the constant interruption to its formation, to which, in the mouth, it is necessarily liable. A case of this nature has been recorded by Frank of Vienna, who has referred to a preparation illustrative of the disease in another instance, preserved in the museum of Hunter.*

The period which glossitis occupies, and its several stages, are very variable in different cases, and influenced by the modifying circumstances already noticed, as well as by the remedial means which may have been adopted. Its disposition to terminate in resolution is in some cases manifested so early as the second or

* *Acta Inst. Clinici Univ. Viennæ, Anno sec. p. 51.*

third day, but seldom before the fifth or sixth. The indications are, a progressive diminution of the morbid bulk of the tongue, and of the pain accompanying it; its surface becoming moister; the thick coat with which it was covered disappearing; a progressive return of power and inclination to use it; with a proportionate decrease or even cessation of febrile symptoms, as well as of those stated to be consequent to plethora in the vessels of the head.

To illustrate the progress of the disease, and its auspicious termination, we subjoin a short sketch of a case described by the writer just alluded to.

A healthy youth, nineteen years of age, was suddenly attacked with febrile symptoms, together with pain in the head and throat, difficulty of deglutition, and cough: these having been neglected, increased, and during the night he experienced very acute pain at the end of the tongue, increasing in extent and severity with its progressive swelling, which was rapid and considerable, filling the whole cavity of the mouth, and rendering him unable to articulate. The following day he complained of pain in the head, especially towards the forehead, with increase of sensibility of the eye to the impression of light; the tongue was remarkable for its red colour, increase of size, rigidity and heat; the patient could neither draw it inwards nor extend it; the sublingual glands and tonsils were tumefied; he was incapable of speech and deglutition; complained of great thirst, had a dry burning skin, and a frequent strong pulse. Copious perspiration of a sour odour came on in the night, the swelling of the tongue and tonsils subsided, and with it the febrile symptoms; the tongue became moist, deglutition easy, and the following day restoration to health seemed to be established.

Suppuration succeeding to glossitis is indicated by some diminution of excitement of the system, with an accession of coldness over the surface of the body, or a distinct rigor, the local pain being somewhat diminished if the abscess be superficial, but the swelling increasing, and at no distant time, in one part or another, becoming particularly prominent. Under the same circumstances the appearance at the pointing part differs from that of the surrounding structure, and to the sense of touch it is soft and elastic, shewing plainly the existence of an abscess, which, if not artificially opened, at length by natural process allows its contents to escape. When, however, the pus is deeply imbedded in the substance of the organ, there being little cellular membrane in the construction of the latter, it separates the parts in proportion to the quantity secreted without diffusing itself, and therefore acts as a wedge, and, from the condensation and sensibility of its structure, the organ is little if at all relieved, as usually happens in most other parts by the effusion of this fluid. By active treatment, however, adopted in the early stage of the disease, suppuration may generally be prevented; but when the presence of pus is ascertained, no time should be lost in relieving the organ of it.

The termination of glossitis in gangrene is

a very rare occurrence, and has happened only in constitutions extremely debilitated by intemperance or disease. The reduced state of the vital powers manifested in the feeble performance of the general functions of the body, and the blackened appearance of the tongue, the peculiar odour, and loss of sensibility, of pain, and of heat, will denote the morbid changes in progress. It has been remarked that the separation of the mortified from the living parts has been particularly rapid when gangrene has taken place in this organ.

A careful consideration of the symptoms of idiopathic glossitis already detailed will afford the readiest index to determine its presence, and to distinguish it from symptomatic inflammation, as well as from other morbid states. The connecting links between local injury and consequent inflammation can be too easily traced to admit of error; and the enlarged states of the tongue arising from the specific operation of mercury, and sometimes consequent to the absorption of particular poisons, are attended with symptoms too peculiar to themselves, and not sufficiently characteristic of idiopathic glossitis, to render any discussion on their diagnostic distinctions necessary. The same remark is applicable to the tumefactions of the tongue which sometimes occur in fevers of a malignant type, as in typhus and variola; or those metastases of inflammation which, though most rarely indeed to this organ, have been found to occur in arthritic and rheumatic cases with its simultaneous subsidence in the part originally affected.

Idiopathic glossitis must at all times be considered a very formidable disease, and the degree of danger, in a previously healthy subject, will be proportionate to the obstacle which the tumefied organ may present to respiration, and to the opportunity which may be offered of subduing the inflammation on which it depends. From active treatment in the early stage a favourable issue may reasonably be anticipated, particularly if a mitigation of symptoms is seen to follow the successive application of remedial means; but if the disease be neglected in the early stage, or the volume of the tongue increase, in resistance to the measures resorted to, respiration will be performed with proportionably greater difficulty, threatening extreme danger to life by suffocation; and in persons predisposed to apoplexy or other cerebral disease, in an additional degree, by the impediment occasioned to the free return of blood from the head, and the consequent aggravation of these diseases. Diminution in the volume of the tongue, whether by artificial means directly applied, or through the medium of the system, will proportionately subtract from the danger and increase the rational hopes of recovery; but if the inflammation should have proceeded to gangrene, the danger to life will be influenced by the probability presented by constitutional circumstances of arresting its progress, and, when effected, by the extent of the mortified part: the tongue being the organ of taste, and necessary to the perfection of speech, of mas-

tication, and of deglutition, these functions will be affected commensurately with the local destruction.

When suppuration has taken place, and the bulk of the tongue is diminished by the natural or artificial evacuation of pus, and the distress of the system lessened by a freer state of respiration and circulation, a recovery may fairly be anticipated; but the proneness in this organ to the development of scirrhus, in constitutions predisposed to it, is a circumstance which the practitioner should be prepared to meet after this or any other excessive local irritation.

Treatment.—The rapid progress of idiopathic inflammation of the tongue, arising spontaneously in a subject previously in good health, and not induced by the action of poisons or mercury, renders it of great importance that the antiphlogistic regimen should be early adopted and actively pursued. Bleeding from a vein in the arm, in proportion to the excitement of the system, or from the external jugular vein when the brain is oppressed or likely to suffer, should be immediately resorted to, and repeated a second or even a third time, at intervals of eight or twelve hours, until the inflammatory action of the system be subdued; other means having been adopted in aid of the same intention. Leeches should be applied in considerable numbers to the tongue itself; and when the oozing of blood has subsided from their wounds, a piece of ice, or very cold water, should be frequently applied. Active purgatives, such as calomel and jalap, or sulphate of magnesia with infusion and tincture of senna, must be given without delay, and their operation aided by a stimulating enema: indeed to keep up the free action of the bowels, so essential in the treatment of this disease, a frequent repetition of this remedy will be necessary if purgatives cannot be swallowed; and, under more favourable circumstances, their counter-excitant action being immediate, they are calculated to prove highly advantageous. The usual diaphoretics and diuretics will be useful adjuvants in effecting the end in view; and, from the small bulk in which they may be given, digitalis and tartarized antimony are to be preferred. Immersion of the feet in hot water, or in some cases even a general hot-bath might be prescribed with advantage. A blister should be early applied across the throat, extending nearly round the inferior margin of the lower jaw, as far as its angles.

When respiration is so obstructed by the augmented bulk of the tongue that its increase or continuance threaten to impede it entirely, two or three deep scarifications must be immediately made from the base to its apex, taking care to avoid the *arteriæ raninæ*, for the means of suppressing excessive hemorrhage from them would probably excite a degree of irritation which would counterbalance the advantages consequent even to a moderate loss of blood.

Several instances of the advantage of incisions in extreme enlargements of the tongue

have been transmitted to us by M. de la Malle.* Camerarius has recorded a case in which the patient was rescued from impending death by this operation; and Zacutus Lusitanus, another of a child, ten years of age, where the usual remedies had failed of affording relief, and the symptoms yielded to deep scarifications. Job a Meekoen, a Dutch surgeon, who lived in the seventeenth century,† adopted this practice on several occasions with the most complete success; and it is probable, as Mr. Samuel Cooper has remarked, that a fatal issue from suffocation, consequent to various kinds of enlargement of the tongue, might in many instances have been averted by its timely adoption. In the twenty-eighth volume of the *Edinburgh Medical and Surgical Journal*, page 77, an interesting case of the disease is recorded, in which the free use of the scalpel was attended with the best effects; allowing an exit for puriform matter. In the twenty-first volume of the same work, page 235, there is another case, illustrative of the advantage of incisions of the tongue, in a case of its inflammation, apparently consequent to suppression of the menstrual discharge from exposure to cold.

It must be acknowledged, however, that incisions are not always successful; and it may be of importance to the practitioner's credit in proposing an operation which at least has the appearance of extreme severity, that he should advise it as essential in the urgency of the patient's circumstances, and the most conducive, though by no means a certain step to his recovery. An example of the inefficacy of this and several other therapeutic agents in a case which proved awfully rapid, terminating fatally within forty-eight hours from its commencement, was detailed in the second volume of the *Lancet* for the year 1827. It occurred in the Winchester Hospital, and had the advantage of the attendance of an eminent surgeon of that establishment in a little more than twelve hours after the earliest symptom of the disease.

If incisions should fail in producing the anticipated relief, there yet remains an alternative by which life may be sustained and an opportunity provided of conducting the disease to a favourable issue: we allude to the operation of bronchotomy, for the success of which in a case of this kind we have the recorded testimony of Mr. Benjamin Bell. The tongue had been alarmingly swollen from the excessive action of mercury, and no relief was obtained, although a variety of remedies had been used, until an opening was made into the trachea to keep up artificial respiration. With the same view Desault would have preferred the introduction of an elastic gum catheter from the nose into the trachea;‡ a method, we conceive, which the preternatural irritability of the parts in particular instances can alone render objectionable.

* *Mém. de l'Acad. de Chirurgie*, vol. v.

† *Dict. des Sciences Méd. Art. Glossite*.

‡ *Œuvres Chir. de Desault*, par Bichat, tom. ii. p. 406.

It will be inferred from our preceding remarks, (and the state of the patient will dispose him little to regret the privation,) that in the early stage of the disease, when the excitement is considerable, stimulating food and drink should be prohibited; it will also be necessary, of course, that the food should be in a soft state, and that both the food and drink should be cool, bland, and unirritating. In some instances the impediment to deglutition may be so great as to make it necessary to administer both medicine and food through the nose by means of a canula passed into the gullet; and, in circumstances requiring such a measure, nutritive injections may be had recourse to.

When the inflammatory stage of the disease has been subdued, and the tongue is assuming its natural appearance, little else will be necessary than care to avoid the direct application of irritating and acrid substances; and, if need be, the restoration to a healthy state by the remedial means severally proper in the particular conditions of those organs the defective actions of which may have served to promote the accession or violence of the disease.

When suppuration has taken place, or is about to do so, it will be necessary to relax in the pursuance of antiphlogistic measures, and, as soon as possible, to make a free aperture for the escape of pus, with a lancet or scalpel. From the observations we have already made on suppuration in this organ, it will be understood that a deep incision may often be necessary to reach the cavity of the abscess. A striking illustration of this has been recorded in the Glasgow Medical Journal, by Mr. Orgill, with other instructive cases of the disease. The patient, a farmer, fifty years of age, had suffered for some days from glossitis, and besides other treatment had undergone local bleeding by cupping and leeches, as well as two incisions *half an inch deep* from as far as the scalpel could be made to reach to the tip of the tongue. The incised wounds bled freely, and the swelling was a good deal reduced, but in the evening of the same day it became as great as ever; it was scarified still more deeply, and a castor-oil enema prescribed; this also gave great relief; but next morning the swelling had returned, with a peculiar lividity at the tip of the diseased half of the organ. An incision *an inch deep* was made with a scalpel, which gave exit to a gush of pus in a very offensive state, and in eight days the patient was well. The sensibility of the organ on the affected side remained imperfect for a year afterwards, but at length was restored.

When the tongue has been relieved of the painful distention occasioned by the impaction of pus, the sanatory quality of the saliva may generally be relied on for the completion of the process of cure. Astringents in most cases will be unnecessarily stimulating, but a simple admixture of honey and barley water, or some gargle equally unirritating, may contribute to the patient's comfort by diluting the saliva, and thus forming a cool and more bland

application. On some occasions it may be requisite to have recourse to other detergents, such as borax or tincture of myrrh in the common form of gargle.

The indications as to constitutional treatment in this stage are, to allay the irritability of the system, and to restore the disordered functions of the body to their healthy state. As the means must be selected on general principles, it would be needless to particularize them here.

When inflammation of the tongue has unfortunately terminated in gangrene,—a very rare occurrence in this rare form of disease,—its treatment is subject to the same laws as gangrene in any other part: reliance, however, is chiefly to be placed on the means of improving the condition of the constitution; though it is to be feared that in most instances there can be little probability of effecting this object. For the particular means we refer to the article *INFLAMMATION*, rather than occupy time and space unnecessarily by any formal detail on a subject which has little notice in the records of medical literature, probably because science has been unavailing in the few opportunities which have occurred for its application.

The enlargements of the tongue, (some extraordinary instances of which are on record,) which have been occasionally consequent to the exhibition of mercury, usually yield to purgatives, or injections of the same nature, bleedings, and the discontinuance of the mercurial medicine. In some cases of extreme obstinacy it may be requisite to make incisions into the organ, or to adopt the other means of treatment which have been proposed: other particulars relative to this state will be discussed under the article *PTYALISM*.

In those tumefied states of the tongue which occur in typhoid and variolous fevers attended with an atonic condition of the system, the local affection requires little consideration apart from the general disease, unless, indeed, the magnitude of the organ should threaten suffocation; when free incisions, in the manner we have already described, and the other mechanical means pointed out, may materially relieve, if not save the patient from impending death.

In such instances as are the results of metastasis, as of gout or rheumatism, the first step will be to invite the inflammation to its original seat, by applying to the latter a sinapism or blister, or by immersion of the extremity in which it may have been situated in hot water, rendered still more stimulating by the addition of flour of mustard or common salt: should this fail in producing the desired effect, or if the habit of the individual should be favorable to the continuance of inflammation, the method of subduing it must be adopted at the same time, bearing in mind that under such circumstances the local affection will partake of the same peculiarities, and require a corresponding consideration, with the general disorder.

(W. Kerr.)

GLOTTIS, SPASM OF THE. This very formidable affection, which is by no means of rare occurrence in infancy, was till of late years but ill understood, being for the most part confounded with croup and other inflammatory affections of the air-passages. One of the first obscure notions of it is that by Millar, under the name of the acute asthma of infants. He seems, in some respects, to have confounded it with the first stage of croup; and yet, if early discovered, he thought it might always be cured by the plentiful exhibition of assafetida, and the subsequent employment of bark.

A further step towards the diagnosis of the disease was made by Underwood, in his division of croup into the chronic or spasmodic and the acute or inflammatory. The former of these, which seems to answer to what is now called spasm of the glottis, he states to have been known to continue so long as two months, and then to have yielded to opium. "Instances have likewise been met with of children crouping for two or three days, and being then seized with whooping-cough, which has instantly removed the croup. These circumstances," he continues, "seem to prove that species of croup to be truly spasmodic. I have seen it frequently in this form attend the cutting of teeth, being then the mere consequence of irritation, as we see cough and various other symptomatic affections induced at this period." In addition to assafetida and bark, Underwood recommends the occasional use of emetics and cicuta—"one or other of which must be persevered in as long as any symptom of the disease, and particularly the croaking noise, shall remain." He seems, however, to have had but a very imperfect notion of the disorder, confounding it in one part of his work with croup, with which it has really no affinity, the membrane lining the larynx presenting no traces of disease on dissection; and treating of it in another place under the head of inward fits, which is an imaginary disease. Dr. Ferriar, likewise, in recognizing a spurious species of croup, seems to have met with the affection in question, though he did not attain to a correct idea of its nature.

One of the first accurate accounts of the disease is that by Dr. John Clarke, in his Commentaries on the Diseases of Children. He describes it under the name of "a peculiar species of convulsion in infant children," often misnamed spasmodic or chronic croup. The child, according to this writer, is suddenly seized with a spasmodic inspiration, consisting of distinct attempts to fill the chest, between each of which a squeaking noise is often made; the eyes are staring, and the child is evidently in great distress. The face and extremities, if the paroxysm continue long, become purple; the head is thrown back and the spine bent, as in opisthotonos; at length a strong inspiration takes place, a fit of crying generally succeeds, and the patient, much exhausted, falls asleep. The paroxysm may occur often in the course of the day, and is most apt to take place on awaking, or on exposure to slight causes of irritation. If neglected, it may go on recurring frequently for two or three months, until at

length general convulsions ensuing, the parents become alarmed. It seldom occurs, he thinks, after the third year, or in children who have lived by suckling alone till they have got some of their teeth, and thus escaped those derangements of the health which are connected with an unsuitable diet in extreme infancy. This, as well as other convulsive affections of children, he ascribes to disease of the brain, which may be induced, he thinks, by overfeeding, keeping the head too hot, the sudden cure of ophthalmia, or of cutaneous eruptions, the occurrence of fevers, &c. In one fatal case he discovered, on dissection, both fulness in the vessels of the brain and water in the ventricles.

A peculiar species of hydrocephalus, ushered in by spasm of the glottis, has been mentioned by Monro; and a case which seems to have been of this kind is also alluded to by Underwood. Gölis, in treating of the predisposing causes of hydrocephalus, places this affection amongst them, and describes it as "a peculiar disorder of respiration, in which infants after sudden waking out of sleep, or from terror or anger, often too without any cause, are suddenly seized with a deep shrill respiration, which for many seconds, sometimes even for minutes, threatens suffocation; the whole body becomes stiff; the face, hands, feet, and particularly the finger and toe-nails black or blue, and the little patients lose their breath and consciousness; at length, however, with a cry of alarm they again recover both."

Dr. Cheyne has given, in the following passage from his work on hydrocephalus, a more satisfactory account of this affection, since called spasm of the glottis, than any of his predecessors:—"Another disease of infancy requires to be briefly adverted to in treating of the diagnosis of hydrocephalus. This disease has been known to some authors under the titles of inward fits, chronic croup, &c. It begins with a crowing inspiration, like that which takes place in the commencement of a paroxysm of pertussis. As at first there are long intervals between these spasmodic inspirations, (several days perhaps;) as they appear to be connected with a disordered stomach and absence of bile in the bowels; to arise from sudden exertion, or fits of passion; and as the child often continues to thrive notwithstanding, the disease is not much attended to. At last, however, the spasmodic inspirations excite just alarm; they occur frequently without any apparent cause, when the child is perfectly tranquil; the complexion becomes purple, insensibility follows, and not unfrequently universal convulsions or rigidity of the muscles, with the thumbs clenched in the hands: these convulsions, in seven instances to my knowledge, have ended in death. However, after continuing many weeks, or even months, this affection often terminates favourably with the cutting of one or more of the teeth, or it may be relieved by effectually scarifying the gums, changing the air and diet, and alternating mercurials with carminative purgatives. The pathognomick of this disease is a crowing inspiration with purple complexion, *not followed by cough*. In some cases this affection is attended not

merely with a permanent clenching of the hand upon the thumb, but also with a very remarkable fixed spasm of the toes, particularly the great toe, which gives a look of swelled deformity to the upper part of the foot." For a further account of this peculiar swelling of the hands and feet, first accurately described by Dr. Kellie, the reader is referred to the article DENTITION, DISEASES OF.

Spasm of the glottis cannot be considered a rare disease, as Cheyne had seen previous to the year 1819, when his work was published, no less than twenty cases, of which one-third were fatal. He, like Clarke, has no doubt that the brain is the seat of the disease; but what is the precise morbid condition of this organ giving rise to these peculiar symptoms, or whether there be any invariable one, has not yet been accurately made out. The results of dissection in three cases are given in the appendix to his work. In the first of these, two tumours, apparently of a scrofulous nature, were found imbedded in the substance of the brain; in the second, the convolutions were nearly obliterated, and the cerebral substance appeared uncommonly firm; in the third, the veins on the surface of the brain were turgid with blood; a considerable quantity of serous fluid existed between the tunica arachnoides and the pia mater, giving a gelatinous appearance to the surface of the hemispheres; whilst about an ounce of water was discovered in the ventricles. Disease of the brain has not, however, always been detected. Thus in two cases mentioned by Dr. Meriman, of children who died in these fits, no appearance of cerebral affection could be discovered. The principal deranged structure was a collection of small glandular swellings in the neck pressing upon the *par vagum*. In none of these cases was there any trace of inflammation in the larynx or trachea.

Gardien's description of this affection, under the title of "*Spasme du Thorax & de la Glotte*," differs in some respects from most other accounts of it. He remarks on the impropriety of many of the names which have been bestowed on it. Thus by Lieutaud and Baumes, who seem to have had a pretty accurate idea of its true nature, and its alliance to convulsive or nervous affections, it has been absurdly called "*catarrhe suffocante*." The appellations of "*acute asthma of children*," employed by Millar, or spasmodic asthma, used by Rush, appear to him equally objectionable. The disorder, as described by Gardien, consists in a spasm of the diaphragm, muscles of the chest and larynx, and is, he thinks, almost always fatal, if suitable remedies be not employed during the commencement of the disorder. It occurs chiefly in children, though in some rare instances it has been observed in adults also, chiefly in nervous women and old persons. The night-mare, or a habit of suddenly awaking from sleep in a state of terror, he looks upon as a premonitory symptom, or as the first stage of the disease. Children who are liable to it are observed to cry very frequently during the day, and are frightened and agitated by the slightest causes. Its

attacks are sudden, and occur chiefly in the night. The appearance of the face during the continuance of the spasm is variable; in some instances being pale as in syncope, whilst in others it has an apoplectic character. It occurs most frequently, he thinks, between two years old and seven; in which he differs from most other writers, as it is usually placed amongst the diseases of early infancy and of dentition. Children who are old enough to explain their sensations complain of a feeling of suffocation and constriction about the chest, as if it were bound with cords, and of palpitations and convulsive efforts of the thorax, with a sense of strangling about the larynx; the respiration is sometimes momentarily interrupted, and is at all times extremely difficult, and accompanied with a peculiar sound, which can be heard at a considerable distance. The stomach and intestines are distended with air, and the patient seems as if he would die of suffocation, if eructations or vomiting did not come to his relief. His description in some of its parts suggests to us the idea of an hysterical affection. Spasm of the glottis, as already stated, has also been mentioned by Dr. Merriman. He thinks it by no means an uncommon affection of children, and attributes it chiefly to improper food and close and confined apartments.

Wichmann, the Hanoverian physician, and Schmalz, in his work on diagnosis, have taken peculiar pains to point out the distinctions which exist between this disease and croup. The latter seems usually to depend on a cold damp air and sudden atmospheric vicissitudes; its inflammatory nature is manifested as well in the character of its symptoms, as by the beneficial effects of antiphlogistic treatment, and by the appearances on dissection. Spasm of the glottis, on the contrary, is excited by passions of the mind and other sources of momentary irritation, existing often in distant parts of the body; catarrhal symptoms form no essential part of the disease; it occurs chiefly in those who have a general disposition to convulsive affections; its attacks are intermittent, and are most susceptible of relief from agents acting on the nervous system; and it presents after death no traces of inflammation in the respiratory organs.

Spasm of the glottis has been described by Mr. Pretty in the Medical and Physical Journal under the singular name of cerebral croup. It has also been noticed by Richter, Henke, Jahn, and several other writers in Germany; and in France it has been treated of by Guersent under the title of "*pseudo-croup nerveux*." Though it has been thus recognized by so many respectable authorities as a distinct and well characterized disease, yet Autenreith and Hecker, and more recently Jurine and Albers, have treated it as a mere modification of croup. From this, however, we repeat, it is broadly distinguished, as well by its intermittent nature as by the usual absence of cough and fever, and by the sudden death which not unfrequently occurs in it. Even if a slight cough happens to co-exist, the disease may still, as Dr. Hamilton has remarked, be satisfactorily distinguished by the cough not being

a peculiarly hoarse one; and by the breathing in the intervals remaining perfectly free.

The latest and by much the best account of the disease, is that by Dr. Marsh. The disorder as described by this writer begins by the muscles of the glottis; but if neglected or mismanaged, it may extend to those of the extremities, and even terminate in universal convulsions. Its occurrence is by no means rare, and its result not unfrequently fatal. It sometimes appears to be a purely idiopathic affection; but in far the greater number of cases, as Dr. Marsh observes, "it is complicated with painful dentition, derangement of the digestive functions, a cachectic state of the system induced by an impure atmosphere, fever, and occasionally with effusion into the ventricles of the brain. The child is observed to awake suddenly from sleep in a state of alarm and agitation, to struggle for breath, and, after repeated efforts, to recover from the paroxysm with a long and sonorous inspiration," usually described by nurses as a whoop or crowing sound. The face is swollen and purplish during the fit. As the disease advances, similar attacks occur even while the child is awake,—“sometimes without any perceptible cause, but more frequently when it is vexed and about to cry.” Robust as well as delicate children are liable to it, but it especially attacks those which are of a passionate and irritable disposition, and the subjects of it are observed to be easily startled even by the slightest noises. It is only in its more advanced stage that Dr. Marsh has observed the peculiar swollen state of the hands and feet, and the rigid contraction of the thumbs and toes already alluded to.

In the treatment of the disease the chief indications consist in removing any complications which may exist, and in improving the general health, and especially the tone of the nervous system. Difficult dentition is a very frequent exciting cause of this affection: when it is suspected to have this origin, the swollen gums must be immediately divided. In those cases where a careful investigation into the state of all the functions of the body detects no complication, a mildly tonic plan of treatment should be had recourse to. The sulphate of quinine, or some of the mineral tonics, are here found very useful. Antispasmodics too often disappoint expectation, and are of very secondary importance in the treatment of the disease: ether and ammonia are the only medicines of this class in which Dr. Clarke had the slightest confidence. The tinctura fuliginis of the older pharmacopœias is spoken of by Dr. Marsh with some commendation. In all cases we should endeavour to improve the general health and strengthen the nervous system by country air, a well regulated diet, and attention to the state of the bowels. By giving the child the advantage of a pure air and of a succession of good nurses during the whole period of dentition, more good has appeared to be done than by all other measures put together. Dr. Marsh remarks that all his cases occurred in children of a scrofulous con-

stitution; a fact which leads him to insist still more strongly on the importance of a pure atmosphere, healthy nutriment, and tonics. Dr. Cheyne, also, as we have seen, dwells much on the utility of change of air and of diet. Free exposure to the open air, and daily sponging the body with cold water, are amongst the most effectual means we possess for lowering the nervous excitability in this and many other spasmodic disorders.

When the convulsions threaten to become general, leeching the temples, cold applications to the head, and fomentation of the extremities, will generally be required. In the case of a delicate child of two years old, mentioned by Marsh, in which the paroxysms were of very frequent occurrence, and were accompanied by general convulsions, a tobacco enema (five grains infused in six ounces of water) was administered; it produced its specific effect in a very marked manner, and no appearance of convulsions was observed for a month after. Removal to the country appeared to confirm the cure. The symptoms, however, recurred on again returning to town to a house which had been recently painted. Several other instances are mentioned, where the disease seems to have been excited by the unhealthy atmosphere of newly painted rooms.

Dr. Merriman is of opinion that this disease, when early attended to, will commonly yield to aperients, so given as to procure at least two copious evacuations daily, together with the continued use of soda, or a strong infusion of burnt sponge, and proper attention to the diet and regimen:—"When the head is manifestly affected, cupping-glasses behind the ears are required; but when the patient has cold, pale, flabby cheeks, abstraction of blood is rather injurious than beneficial." Dr. Hamilton has found Dalby's carminative a useful medicine in this affection after the bowels have first been freely opened. We have known the disorder, after resisting the influence of purgatives and change of air, cease finally on the occurrence of a spontaneous diarrhœa.

Spasm of the glottis has occasionally been mistaken for an inflammatory affection of the lungs or air-passages, and been much exasperated by a consequent perseverance in the antiphlogistic treatment, and by confinement to the close air of a heated apartment. Even in its simplest and mildest form it should never be neglected, as, in the absence of every complication, the spasm of the muscles of the larynx alone has often proved suddenly fatal. Dr. Johnson knew a case recovered by the immediate employment of artificial respiration, after death had apparently taken place.

Before terminating this article, we may state that fatal spasm of the glottis in adults occasionally takes place, under the influence of irritating causes in the neighbourhood of the larynx. Thus, in an interesting case recorded by Mr. Kirby, spasm of the glottis and death were caused by the irritation of a mouthful of food sticking in the œsophagus; and we have seen a patient with many of the symptoms of acute laryngitis die rather unexpectedly,

when, on dissection, very little if any redness or swelling were discovered in the membrane lining the larynx, and scarcely any other morbid appearance than one or two minute ulcers. It is probable that the fatal result, as well as the sonorous breathing, and many of the other symptoms in such cases, depend on a spasmodic contraction of the glottis.

(W. B. Joy.)

GOUT, *gutta, la goutte*, a drop or defluxion. A name is of slight importance, provided it does not mislead by imputing to a disease a hypothetical character. If used only to express the individuality assigned, for purposes of convenience, to an aggregate of functional disturbances or structural lesions, and limited to this sense without involving any speculative conjectures respecting the cause or nature of disease, it need not be rigidly criticised. That which heads the present article, while it is one of the most ancient, being traceable so far back as the thirteenth century, and the most generally adopted, a corresponding term having found its way into all the languages of Europe, is also the one in common use to designate the disease; and as the false theory which gave rise to it has been long exploded, and is now incapable of biasing any one's judgment, it seems little worth while to change it for any other, especially as, of the substitutes introduced or proposed, none is so unexceptionable as to entitle it to a preference.

An elaborate treatise on gout would be unsuitable to the present purpose, while it would be valueless if it could be introduced. To record all that has been said in the lapse of centuries would be a wearisome labour to the writer, and profitless to the reader. Much has been written which may well be passed over. The facts are few, the speculations many, and these too often the mere phantasms of the brain. The former are the same now that they ever were, and therefore cognizable by every observer; and far better is it to study them in the book of nature than to take them on trust from any authority, however high: the latter have produced but little worth remembering; theories have chased each other like shadows in a magic lantern, none abiding to announce to us the essential nature of gout. After ages of enquiry, we know it only by the order and character of its phenomena, and have yet to learn its intimate nature or the special cause which produces it. Happily the knowledge within our reach is sufficient to guide us to much useful practice, as well in averting accessions of the malady as in mitigating them when they do occur, and in preventing the disorganization and decrepitude to which gout, when neglected or maltreated, so often consigns its miserable victims. If, from our inability to penetrate nature in her inmost recesses, we cannot detect the essence of gout, we can at least note the succession and character of the phenomena which constitute it; we can mark the deviations from health which precede and attend the attack,

and, by contrasting them with the healthy condition, can arrive at some knowledge of what is amiss: we can thus direct our efforts to restoring healthy function where this is sensibly impaired, and by so doing can second the efforts of nature in remedying the special disorder, even when ignorant of what essentially produces it. In fine, by adopting a pathology founded solely on facts unalloyed by hypotheses, and conformable to all that we know of the physiology of animal life, we may establish a system of treatment supported by rational principles, and capable of rendering much valuable service to those who need our assistance, and look to us for relief.

We have it in our power in a great degree to avert the accession of the gouty paroxysm by correcting that state of the constitution which ministers to it; we can greatly mitigate the sufferings of the attack, abridge its duration, and prolong the period of exemption; by so doing we can prevent those horrid disorganizations which protracted or oft renewed gout so constantly occasions, and also obviate still more fatal consequences which result when gouty action extends to vital organs and other parts essential to well being. The brain, lungs, heart, stomach, liver, kidneys, may any or all participate in the derangements occasioned by unrelieved or maltreated gout; and the sufferings and danger which thence result may be numbered among the most formidable to which disease can subject the animal frame. Palsy, epilepsy, gravel, and other direful infictions are too often the attendants on protracted gout, and intensely do they aggravate its sufferings. These views are hastily sketched, for the purpose, not of magnifying the disease or attaching to it an undue importance, but of claiming for it that scrutinising investigation, vigilant observation, and sober judgment which may bring its practical treatment within the pale of rational principles, and divest the subject of the mysticism which has been too long suffered to surround it, to the discredit of medical science and the encouragement of charlatany.

On no subject has empiricism been more assiduously or more mischievously pursued; and where its nostrums have not proved absurd from their inertness, they have been too often pernicious from their activity: witness the numberless victims who fell a sacrifice to the delusive efficacy of the *eau medicinale*. Until the treatment of gout shall be established on the same principles which are found applicable to all other diseases; until the contemplation of its inscrutable, or at least undiscovered, essence shall be superseded by a fixed attention to its obvious and intelligible phenomena, and the proper treatment which these demand be adopted generally and systematically by the profession, quackery will continue to practice its deceptions, and gouty sufferers, hopeless of relief from the regular practitioner, to surrender themselves the willing dupes of every confident pretender.

A history of gout that would comprise all its alleged forms and modifications would be both tedious and uninteresting; nay, instead

of elucidating, it would but obscure the subject, involving it in inextricable confusion. Much that has been attributed to gout belongs not to the special disease so much as to incidental derangements, either antecedent to, coincident with, or resulting from it, and no more an integrant part of gout than when they occur in connexion with any other malady. The incidental derangements of a gouty habit are numerous enough, and often to be met with; but it can serve no good purpose to represent all these as characteristic of gout, which, on the contrary, will be best and most clearly comprehended when viewed in its natural form, divested of those complications which, however occasionally intermixed, do not necessarily belong to it. It has been too much the custom to attribute every morbid action occurring in a gouty habit to the influence of gout; and, however obvious their nature or character, to render their treatment subservient to the notions of gout which the medical attendant chanced to entertain. In this way have the apprehension of debility, the belief of a tonic treatment being requisite in gout, and the fear of injuring the constitution by any interference with the gouty paroxysm, misled many into pursuing a stimulant regimen under circumstances which, but for this delusion, would have been seen to indicate a very opposite course; and to the conflicting experience derived from observations made under such misconceptions, may be ascribed much of the uncertainty and caprice which mark the treatment of gout, both popular and professional, even at the present day.

The best history of gout for all useful purposes must be that which represents the disease in its simplest form, giving such a description as will enable the young practitioner to recognise it when presented to his view. This being illustrated, and the principles of treatment explained, the various modifications may then be advantageously discussed in connexion with the derangements which occasion them, and with the treatment which they respectively require; in which course of enquiry it cannot fail to be remarked how much this treatment is dependent on the same general principles which guide the practice in all other diseases, and how very little consideration it admits for the special nature or character of gout.

The definition of Cullen characterises the disease clearly and succinctly. "*Morbus hereditarius, oriens sine causa externa evidente, sed præeunte plerumque ventriculi affectione insolita, pyrexia, dolor ad articulum, et plerumque pedis pollice, certe pedum et manuum juncturis potissimum infestus, per intervalla revertens, et sæpe cum ventriculi et aliarum internarum partium affectionibus alternans.*" That this as a definition is open to objections we admit. As a description of the disease, however, at once concise and correct, it seems to answer every purpose; and we are not aware of any preferable or less exceptionable character of the malady having been yet proposed. The object of a definition is so to

characterise a disease that the name used to denote it shall be applied always to the same morbid condition. But it is a general character only that can be thus assigned. Perfect accuracy is not within the compass of any definition; and it is fruitless to cavil at imperfections of nosology, when of the branch of science which classifies disease the very foundations are yet undetermined. It may be confidently alleged that of all the methodic classifications yet proposed, not one rests on a stable basis; and both physiology and pathology must be greatly advanced ere any arrangement bordering on a natural and scientific classification of diseases can be practicable. The derangements of the constitution which usher in diseases, the local disturbance to which they give rise, and the reaction by which these aggravate and complete the disordered state in which they originate, are too little understood for any classification of diseases founded on their essential nature or character to be yet attempted. To the labours of the pathological anatomists now so diligently pursued, and to the lights which these shed on morbid actions, and the lesions which result from them, must we look for guidance in this respect if the object is ever to be attained. So unsettled are opinions respecting diseases of the most frequent and extensive occurrence, that it is yet disputed whether fever is a local or constitutional disease; and this ambiguity is likely to endure so long as consideration of diseased conditions of the frame is taken up at the advanced period at which a nosological disease presents itself, without sufficient regard being had to the previous deterioration of health to which so many of these morbid conditions are traceable, and without a clear knowledge of which their nature and progress never can be thoroughly understood.

Much of the complexity displayed in any minute history of gout results from several circumstances being comprised which do not essentially belong to it. Left as it has been to work out its own cure, derangements have ensued in its unchecked progress, which a more efficient treatment of the incipient disease would have wholly prevented, and which should, therefore, be considered rather as contingent and derivative than as forming a primary or essential part of the malady. Peculiarity of constitution, too, whether natural or acquired, continually varies the aspect of the disease; and here to discriminate what is truly gouty from what is but casual is surely preferable to confounding the whole assemblage of symptoms by representing them as all characteristic of gout. The best mode of imparting just and clear ideas on the subject seems to be, to discuss first the disease in its simplest form; and having illustrated, so far as our knowledge permits, its nature and treatment, to extend enquiry to those complications which protracted malady or peculiarity of constitution occasion, instead of regarding these as distinct and peculiar varieties; in which course of investigation the several mo-

difications distinguished as atonic, retrocedent, and misplaced gout, will be necessarily included.

Histories of gout have been rendered with a minuteness of detail highly creditable to those by whose patient observation and faithful delineation they have been supplied. So copious has been the record of symptoms, whether antecedent to, accompanying, or consequent on a paroxysm, that there is scarcely a derangement of the frame which has not at one time or other been noticed and included. It is full time to lay aside this tedious and profitless minuteness,—to classify those individual symptoms according to the functional derangements which they indicate,—to ascend from the manifestations to the causes which produce them, tracing to the disordered functions the several symptoms which denote their disturbance,—to look to the nature and character of such disturbances, and their connexion with the disordered functions, as the only real source of useful knowledge, the only sure guide to rational or effectual practice in this or any other disease,—to distinguish what really belongs to the disease from mere contingencies, dependent not on the specific cause of gout, but on deviations from health local or constitutional which have no necessary connexion with it, and which require to be treated precisely as if they occurred independently or in connexion with any other malady. Divested of this source of confusion and obscurity, gout becomes as intelligible as are many diseases with which we consider ourselves better acquainted; and though after all our investigations the influencing cause of its peculiar and distinctive character is still a mystery, we may attain quite as intimate a knowledge of its pathology, as far as regards practical utility, as we possess of small-pox, rheumatism, or any other disease of the intimate nature of which we are ignorant, and which we are content to know only through the medium of the constitutional and local disturbances which mark their accession and progress.

In this view a paroxysm of gout can be regarded only as a constitutional disturbance of an inflammatory character, attended with local inflammation of a peculiar kind in one or more joints, running a determinate course, and in the earlier accessions terminating in health, for the most part within a very few days. Such being the character of simple gout, there is no reason why the complications so much dwelt on should be considered as specially belonging to it, or regarded otherwise than as accidents arising from peculiarity of constitution, contingent derangements of health, or the lesions or morbid tendencies entailed by preceding accessions.

That the paroxysm of gout manifests invariably an inflammatory character is a truth which all admit. The inflammation both local and constitutional occurs in every variety of degree; still an inflammatory character marks the whole. In consequence of the disease being identified with the local inflammation, and supposed to commence only when this appears, the seizure is generally represented as

taking place suddenly, the previous good health being gratuitously assumed. This, however, is a great fallacy, no disease evincing so much constitutional disturbance or local inflammation, arising from a cause acknowledged to exist within the body itself, being ever of sudden occurrence. Ample warnings of the approach always exist, and would admit of ready detection, but that the parties, unsuspicious of what is pending, or thinking lightly of the unhealthy deviations, overlook or disregard them; and as medical aid is not sought until the accession of the paroxysm, the premonitory indications are rarely submitted to the observation of the medical practitioner: whence a stage of the disease of the first importance, and that which is calculated to throw light on all the subsequent changes, has not received that scrutiny to which it is eminently entitled, nor been allowed the share which it ought to have, both in determining the true pathology of gout, and establishing the practice best suited to its relief.

In the active gout of robust habits, the plethoric state of constitution attendant has been too conspicuous to be overlooked, and accordingly it has received its full share of attention, although the indications of treatment which it presented have not always been acted on to the extent which they ought. It is of importance to understand that in cases where plethora is less obvious, its existence is not the less real nor the less entitled to the practitioner's serious attention. The subject of plethora, its intrinsic nature, modifications, and phenomena, is too extensive to be introduced in this place, a separate discussion being required to elucidate it, which will be found under its proper head. So connected, however, is plethora with gout, that a brief notice of its pathology becomes a necessary introduction to the further consideration of this disease.

The elements of nutrition being supplied to every part of the body by the blood, and this deriving its nutritive matter from the aliment taken, it is obvious that redundancy of nutritive matter may take place in the blood, either from sustenance being inordinately taken, or from a diminished expenditure of it in the ordinary appropriations. In either case the healthy proportions of the elements of which blood consists are altered, and a corresponding effect is produced on the several processes to which the blood is subservient. An accurate investigation of the actions and changes thus induced would go far to explain the origin and progress of many diseases. They should be traced, not by speculative conjectures of what might be ingeniously supposed to take place, but by carefully noting the phenomena which indicate them, and, by induction from well-ascertained facts, guided by a sound physiology, ascending to that point which connects the state of health with the morbid changes. These phenomena have been much overlooked or misconceived, and the semblance of debility which they present has been the source of much bad practice.

The plethora of a healthy and vigorous habit is familiar to all, is readily acknowledged, and seldom misunderstood. That which arises in habits more weakly by nature or depraved by vitiating influences, is less known, and its appropriate phenomena are more liable to mislead. When fulness of habit arising from redundant nutriment takes place in a healthy constitution, its earliest effects display what may be termed exuberance of health rather than a state of disease. The several functions of the body are more vigorously performed, the nutrition of its several structures is more abundant, and it acquires increase of bulk, especially if the habits of life are not of an activity capable of rendering the appropriation of blood in the several secretions commensurate with the nutriment inordinately supplied. Though this state cannot well be denominated disease, it yet approaches very nearly to the confines, as is continually exemplified in instances where acute diseases of formidable intensity assail persons considered as being antecedently in unusually good health. If the excess be casual or inconsiderable, the self-adjusting powers of the body are amply sufficient to dispose of it so as to prevent the accession of actual disease. And this is done simply by the stimulus of the too nutritive blood exciting the several secretories and excretories to an increased exercise of their several functions. But when, from extent or continuance, the excess is such as to urge these powers beyond a certain point, then these corrective energies fail, and irregular actions and distributions of blood take place, laying the foundation of a large proportion of the special diseases to which the human body is liable. The general character of the diseases thus induced is congestive or inflammatory; by depletion and abstinence the disturbing cause is corrected, and, thus relieved, the natural powers of the constitution soon re-establish a state of health. The more early such relief is afforded, the more prompt and effectual will it be, and the more certainly will those lesions and derangements be averted which protracted plethora is sure sooner or later to occasion. But to relieve it thus early so as to obtain these advantages, it is necessary to be able to recognise its existence by those evidences which denote it, antecedently to the stage of excitement known to us as fever or inflammation. These evidences present an equivocal character to those who have not closely observed the rise and progress of plethora, and they are continually misconceived as rather indicating a state of debility requiring support from nutriment and stimulants, than as calling for abstinence and depletion. When plethora (by which is to be understood not a mere redundancy in the quantity of the blood, but an excess in the proportion of the elements, chiefly the gluten, which supply nutritive matter to the several tissues) increases so as to exceed what the excited energies of the frame can healthfully dispose of, these energies, incapable of sustained over-exertion, become weakened, and a condition results which is very liable to be

confounded with pure debility. The pulse becomes low, oppressed, irregular, and a state of general languor is experienced. Sooner or later this condition passes into one of permanently increased action of the bloodvessels, attended with additional phenomena, the assemblage of which constitutes that state to which we apply the terms fever and inflammation. For the full consideration of this subject we must refer to the article PLETHORA, as it would encumber too much the present essay. Some notice of it in this place was indispensable from its connexion with gout, and the necessity of referring to it both in elucidating the character and progress of the disease, and in establishing the principles on which the treatment should be conducted.

A paroxysm of gout is seen to consist of a peculiar constitutional disturbance terminating in a local inflammation, the occurrence of which latter, so far as the simple paroxysm is concerned, seems the natural remedy of the preceding disturbance. If the various derangements which usher in an attack of gout, instead of being promiscuously enumerated with a minuteness and to an extent which confound all clear conception, were classed according to the functions severally depraved, the representation would be much more simple and intelligible. All of them admit of being traced to lesions of the circulation, alimentary canal, the nervous system, and the several secretory and excretory organs. Pursuing the inquiry, it is not difficult to mark the connexion of these with each other, or to detect the primary derangement in which they have their origin. Excess of nutritive matter in the blood, whether absolute or relative, has been seen to disturb the circulation, occasioning, first, a high activity of healthy function; secondly, an interval of diminished energy; and, lastly, a state of permanent excitement. By absolute excess is meant that which would be excessive in the most healthy state of the individual constitution, and which is always the result of inordinate nutrition; by relative, that which, though it might not exceed what a state of health with active exercise might safely endure, is yet relatively redundant when health has from any cause declined, or when from defect of wholesome exercise, the healthful appropriation has been more or less impeded. Under all these states of vascular action the several secretory and excretory functions become first excited and afterwards more or less depraved, and nervous affections of various kinds ensue, produced either by irritation of the splanchnic nerves, giving rise to endless sympathies, or by disturbance of the brain itself, occasioned either by too rapid circulation, or by remora of blood within it. The series of phenomena here noticed may be traced with considerable precision and in the ordinary succession, although, so far as regards the nervous derangements, these admit of considerable variation. The best proof of the correctness of these views is to be found in the efficacy of the practice to which they lead.

It is this plethoric state of constitution that

invariably leads to the accession of gout, and the premonitory signs of the approaching paroxysm may always be detected by those who seek them in the derangements of function which indicate a state of plethora. These could not have been so long considered as questionable were it not for the delusive appearance which some of the phenomena present, the suspicion of debility which they arouse, and the timidity of the class of patients most subject to gout, which, shrinking from all active treatment, and clinging to accustomed indulgences, has in all ages, even the present, biased the judgments of practitioners; who, even when they see the right mode of treating gout, are unable to pursue it, and compelled to follow the established routine, however inert or mischievous, until from never witnessing the salutary effects of simple and direct treatment, they lose sight of its advantages, and at length cease to be conscious of any such being attainable.

A state of plethora, absolute or relative, precedes every accession of gout, and is the principal if not immediate cause of it. The intensity and duration of the paroxysm, too, are dependent on the degree of plethora prevailing, although other circumstances may contribute to prolong the attack. But, notwithstanding this, gout is not simply plethora leading to or ending in local inflammation. There is something more from which gout derives its distinctive character, and this ideal, at least unexplained existence it is which constitutes the essence of gout. As we are utterly ignorant of it, save through the modifications of inflammation which it produces, our best and safest course, so long as this ignorance continues, is to pay no regard to it farther than to observe the phenomena which denote its existence; to mark their order and succession, with the deviations from the ordinary course of inflammation which they display; and to preserve our practical procedures free from any influences derived from mere speculations of this unknown cause, however ingenious, resting them solely on well established facts and enlightened experience.

In simple gout we know of no good reason why the treatment applicable to the same degree of general fever and local inflammation occurring from other causes should not be employed. Its general safety and efficacy we can faithfully attest, nor are we aware of any peculiar caution being required beyond what the accompanying state of constitution and the attendant symptoms must necessarily suggest. In all diseases, however inflammatory, the state of constitution requires to be taken into account in judging the activity of practice that may be safely ventured on; and the same consideration is needed in gout, but assuredly none is due in this respect to the imputed essence of gout, nor to the apprehension of interfering with it which has been too long suffered to paralyze the efforts of the practitioner in contending with this hitherto unconquerable foe.

The constitutional disturbance which ushers in gout leads to a local inflammation, after the occurrence of which the constitutional derange-

ments subside. As this inflammation in the earlier accessions quickly subsides, leaving the parts affected unimpaired, it is fair to consider it the crisis of the malady, and also its natural cure; though how it accomplishes this cure is a mystery which we are unable to solve. And were the disease to end here, the interference of art would be superfluous and improper; but it is far otherwise: renewed plethora leads to successive attacks; these progressively increase in intensity, duration, and extent of ravage; and woful experience amply proves that the mere efforts of nature, unaided by regimen, are quite incapable of extinguishing gout. Whenever gout occurs, therefore, it is always expedient so to assist nature as to accomplish more than her unaided efforts are capable of performing, both in rendering the attack milder and the recovery more perfect. The more speedily the constitutional disturbance is corrected, the less is the risk incurred of the gouty diathesis becoming confirmed, and the greater the security against the derivative ailments entailed by protracted or oft renewed gout; the sooner the local inflammation is subdued, the less will be the ravages made in the structure of the inflamed joints, and consequently the less the liability to that decrepitude which rigidity of joints, whether arising from thickened ligaments, effusion into the bursæ, or the deposit of solid concretions, occasions.

The gouty paroxysm, involving as it does a state of constitutional plethora, attended with local inflammation, and a latent influence directing and modifying that inflammation, must always be contemplated in its compound character; but so far as practice is concerned, this must be regulated by reference to the inflammatory state, which is fully within our comprehension, rather than to the latent influence, of which we know nothing. The former, with sure and steady light, directs us safely on our way; the latter is much too indistinctly seen to afford us any guidance. If the first attack of gout were treated with due activity, as an accession so decidedly inflammatory would assuredly be were it not for the prejudices so long and so pertinaciously maintained, and if the diet and regimen were afterwards regulated as the tendencies of the constitution and the degree of the gouty diathesis would demand, the future ravages of the malady would be slight indeed, and its victims few. To disregard of the real nature of the malady, to timidity and inefficient treatment of it when it first occurs, and to the pernicious effects of ease and luxurious indulgence in the intervals, when active exercise and abstemious regimen afford the only means of counteracting the morbid tendencies that exist, may be traced all those horrid disorganizations and broken constitutions which have rendered gout the opprobrium of medical science.

As two elements concur in the formation of gout, the plethoric state and the unknown influence, it is clear that these may combine in every variety of proportion, and that the results will be conformable to the degree in which either may prevail. Where the gouty predis-

position is strong, a slight degree of plethora will suffice to call it into activity; where the plethora is inordinate, a slight degree of gouty diathesis will give that direction and character to inflammatory action which will identify it with gout. In either case it is the plethora and inflammatory state which chiefly claim the practitioner's attention, and to which his remedies can be most beneficially directed,—with this difference, that in proportion as the diathesis, whether hereditary or acquired, is strongly marked, should the means corrective of plethora and inflammation be assiduously and perseveringly employed, within those limits which a sound discretion would enjoin. In the distinction, so much insisted on in the foregoing pages, between the constitutional condition and special influence which conjointly minister to gout, it is by no means designed to withdraw attention wholly from the latter, or to decry any enquiry by which a precise knowledge of it may be attained. The discovery, whenever made, must render essential service, and no opportunity of effecting it should be neglected. But until profound research or some fortunate accident shall disclose what has hitherto been hidden from our view, we must be content, if we would render our practice either consistent or effective, to follow that guidance which our familiar acquaintance with febrile and inflammatory affections so amply affords.

If the character of gout in its simplest form and highest intensity be unequivocally inflammatory, it is difficult to conceive why its various shades and modifications should be otherwise regarded. The differences are not greater than are continually met with in several other diseases; nor, when they do occur, is there any difficulty in referring the peculiarities to the particular constitution, the effects of previous disease, and other contingent circumstances amply sufficient to account for them. These circumstances may, and in numberless instances do require that the appropriate remedies of inflammation should be applied with caution; but they can by no means warrant the principles of treatment founded on the inflammatory nature of gout being wholly reversed, as is too often witnessed. There has been too much disposition, arising from timidity, ignorance, and false theory, to transfer to simple active gout the cautions and the apprehension of interference which contemplation of the complex and less active modifications has given rise to. The converse of this reasoning, if more generally adopted, would have led to happier results, to more prompt and effectual relief of gouty sufferers, and to a juster estimate of the practical benefits capable of being afforded by medical science.

Having thus prepared the way for a clear and intelligible discussion of gout, we shall proceed to treat the subject more methodically, and, so far as we are able, elucidate the circumstances which give rise to its various degrees and modifications, so as to enable the young practitioner to discriminate in the use of his remedies, and neither to withhold from gout the treatment which its prevailing character de-

mands, nor to carry this beyond the point which sound experience warrants.

The paroxysm of gout has already been cursorily noticed. It is necessary to present it more fully, so as to mark distinctly the peculiarities which distinguish it from simple articular inflammation. Cullen defines regular gout as, "*podagra cum inflammatione artuum satis vehementi, per aliquot dies perstante et paulatim cum tumore pruritu et desquamatione partis recedente.*" Accounts of the symptoms which precede and accompany the fit are rendered by all authors who have treated of the disease, to whose works we must refer those who wish to know all the morbid phenomena which may precede or attend the paroxysm. Sydenham, who, when he wrote his treatise on the gout, had been a personal sufferer from the malady for four-and-thirty years, has detailed those symptoms with a minuteness and accuracy that cannot be surpassed. He represents the attacks of gout as in general coming on suddenly, with scarcely any signs of its approach, except that the patient has been afflicted for some weeks before with bad digestion, crudities of stomach, and much flatulency and heaviness, which gradually increase until the fit begins; this, however, being preceded for a few days by a numbness of the thighs and a sort of descent of flatulencies through the fleshy parts thereof, along with convulsive motions; and the day preceding the fit the appetite is sharp but preternatural. The patient goes to bed and sleeps naturally until about two in the morning, when he is awakened by a pain which usually seizes the great toe, but sometimes the heel, the calf of the leg, or the ankle. The pain resembles that of a dislocated bone, and is attended with a sensation as if water just warm were poured on the membranes of the affected part; and these symptoms are immediately succeeded by a chilliness, shivering, and slight fever. The chilliness and shivering abate as the pain increases, which is mild in the beginning, but grows gradually more violent every hour, and comes to its height towards evening, adapting itself to the numerous bones of the tarsus, the ligaments whereof it affects, sometimes resembling a tension or laceration of these ligaments, sometimes the gnawing of a dog, and sometimes a weight and coarctation or contraction of the membranes of the part affected, which become so exquisitely painful as not to endure the weight of the clothes, or the shaking of the room from a person's walking thereon; and hence the night is not only passed in pain, but likewise with a restless removal of the part affected from one place to another, and a continual change of posture. Nor does the perpetual restlessness of the body which always accompanies the fit, and especially in the beginning, fall short of the agitation and pain of the gouty limb. Hence numberless fruitless endeavours are used to ease the pain by continually changing the situation of the body and the part affected, which, notwithstanding, abates not until two or three in the morning, that is, till after twenty-four hours from the first approach

of the fit, when the patient is suddenly relieved by a moderate digestion and some dissipation of the peccant matter, though he falsely judges the ease to proceed from the last position of the part affected; and being now in a breathing sweat, he falls asleep, and upon waking he finds the pain much abated, and the part affected to be then swelled; whereas before only a remarkable swelling of the veins thereof appeared, as is usual in all gouty fits. Such is Sydenham's description, which we have given in his own words as translated, being reluctant to weaken the force of such graphic delineation by any attempt at abridgment. The little admixture of theory evinced in the reference to digestion and peccant matter, cannot detract from the truth or value of this clear and circumstantial recital. For some days after this accession he represents that slighter degrees of pain and fever recur each evening, continuing until morning, after which all disease ceases, and the patient is restored to more vigorous health both of body and mind than he had antecedently experienced. This is the simplest course of a gouty paroxysm, and that which it usually runs on a first attack. On succeeding seizures, especially when the constitution is robust and plethoric, inflammation, on subsiding in one joint, becomes renewed in another, and eventually several joints are attacked in succession, and often two or more at the same time; so that in this progress every variety of intensity, extension, and duration becomes ultimately encountered. To dwell on these different degrees would be useless, as they are all but extensions and modifications of the simple paroxysm, requiring no modification of treatment beyond what the severity of the attack and the existing state of constitution enjoin.

The attack of gout is said to take place suddenly, and with scarcely any previous warning. Yet the very accounts which so represent it give abundance of premonitory indications, which are stated as preceding the attack even for some weeks. Dyspeptic derangements, with some nervous ailments, are the precursors usually noticed; and the assertion of good health existing up to the period of the gouty accession seems to have rested, not on any positive examination or knowledge of the fact, but on the mere circumstance of the patient not having his consciousness so aroused by any precise or considerable indisposition as to complain of being ill. So far as we have had opportunity of noticing the state of health which precedes the gouty seizure, we utterly disbelieve this assertion, and are satisfied that if the phenomena which mark incipient plethora and progressive febrile action were duly noticed, the same constitutional derangements which precede other inflammatory affections would be found uniformly to usher in gout. Disturbances of gastric and nervous functions are acknowledged; those of the circulation would be no less manifest if practitioners were more familiarly acquainted with the changes which the pulse undergoes in progressive plethora, from the stage of oppression marked by a pulse low and irregular both in force and

frequency, to that of the permanently excited action of fever or inflammation evinced by a quick pulse, hot skin, and furred tongue.

One of the earliest instances of the introductory stage of gout which came under our observation occurred many years ago, and served to confirm impressions which our mind had for some years preceding been gradually receiving, from a careful observation not only of gout, but of all other inflammatory diseases. The case was detailed in some pathological and practical observations published in the *Edinburgh Medical and Surgical Journal* in 1814, from which we now extract it. It will shew at least how much constitutional disturbance, perfectly obvious and unquestionable, may exist while the person affected is unconscious of being otherwise than in perfect health. "A gentleman about forty years old, and of full habit, had been subject to gout for several years. He arrived in this country in the course of last summer from America, where he had suffered several attacks of the disease. The treatment experienced under them I cannot specify, but in the intervals he was enjoined to take a pint of wine daily, in consequence of his gouty habit. This he acquiesced in from unwillingness to put his own judgment in competition with that of his physician, although he disliked the remedy, and thought himself always worse both from wine and full living. He called on me in autumn last, to know if he should drink the Bath waters, as recommended by his American physician, at the same time stating himself to be particularly well and free from complaint. I found his pulse full, strong, and nearly 100, and his tongue whiter than it ought to be. I consequently discountenanced any trial of Bath waters, and gave my opinion that he stood much more in need of bloodletting and evacuations. As he professed himself, however, to be so very well, I did not feel myself warranted in pressing this, though satisfied that his habit of body approached much too nearly to a state of inflammation. This conversation took place on Wednesday, the 14th of October; and on Thursday, the 15th, he was attacked with gout in the right knee. On Friday, a second attack took place in the left foot; and on Saturday I was sent for. I found his skin hot, tongue white, and pulse 106, full and strong. Sixteen ounces of blood were drawn, after which the pulse fell to 84. A full dose of a purgative, consisting of colocynth, calomel, and antimonial powder, was given at bed-time, and a solution of Epsom salt the following morning. On Sunday he was better in every respect, but the pulse was again up to 96. It evinced clearly a necessity for further bloodletting; but as the purgative was then operating and the local disease abating, I was satisfied to order the bloodletting to be repeated the following morning. It was not in time, however, to avert a third attack, which took place during the night in the right elbow. Next morning I found the pulse as much reduced as if bloodletting had not been practised, although it did not take place in consequence of the state of

the arm. Whether this effect was owing to relief to the general circulation being afforded by the formation of the local disease which had occurred during the night, or whether it proceeded from a degree of syncope and nausea which were experienced at first rising, or whether they were all dependent on some common cause, I shall not pretend to determine. At this time the knee was nearly well and the foot much better; and as the tendency to syncope had not entirely gone off, and he felt reluctant to have both arms incapacitated, he expressed a wish that the bloodletting might be deferred until the gouty arm got better. On Tuesday the foot was almost well, and the elbow getting better. The pulse, however, was again 96, full and oppressed, which determined me against incurring any further risk, and on having recourse once more to the lancet. About fourteen ounces of blood were taken, which induced some faintness. On Wednesday the pulse was 84, and there was no renewal of gout. Purgatives, salines, and low living were the only means employed thenceforward, and from this period he rapidly recovered. On the 26th he walked to my house, and could have done so some days earlier had the weather permitted. He expressed himself much gratified at the treatment he had undergone, as confirming the correctness of those views of the disease which he had always entertained, and declared to me that he had never thrown off such an attack so quickly, so perfectly, or with such unimpaired powers."

On the treatment pursued in this case we shall only remark, that had it occurred to us later in life, when our judgment was more matured, and our conviction of the safety and efficacy of active practice in gout confirmed by more ample experience, we should have hesitated less in affording the appropriate relief, and the result would have been still more favourable. The case, independently of the result, is of value on two accounts,—as exhibiting the unequivocal state of constitutional inflammation which precedes the gouty paroxysm, and as shewing how far constitutional disturbance may prevail without the party having any consciousness of its existence. Were it not for the accidental examination made on the day preceding the attack, this person on the evidence of his own consciousness would have been pronounced in perfect health up to the period of the gouty accession. The inferences deducible from the facts here stated have been uniformly confirmed by all that we have seen of gout from that period to the present time.

Although gout, then, may arise without any evident external cause, a cause sufficiently manifest may be discovered in the attendant state of constitution by those who seek for it. It is true that where the gouty diathesis is strong, a slight degree of plethora may suffice to call it into activity, and in these instances the plethora and inflammatory tendency may, if not closely investigated or if only loosely observed,

escape detection. Our firm persuasion, however, impressed by all that we have seen of the disease, is, that in every case of spontaneously occurring gout, more or less plethora either absolute or relative, and of inflammatory tendency sufficiently discernible, precedes the gouty accession; and that in proportion as this state is borne in mind, and the treatment regulated with reference to it, will the fit be more speedily and effectually relieved, the period of exemption prolonged, the ravages in the joints prevented, and the contingent maladies averted. From this view of the subject, it is clear that high feeding and indolence are very properly enumerated among the predisposing causes of gout. From these fullness of habit arises, and this, as will be more fully shewn in the article PLETHORA, leads to a series of phenomena, which indicate first an overloaded and oppressed state of circulation, and afterwards one of increased action. When the latter attains its full activity, it constitutes what we call fever or inflammation, and any accident may determine the part which is to suffer most, and the function which is to be most depraved. When this plethoric and inflammatory state arises in a gouty habit, the result is an accession of the disease.

A remarkable peculiarity of gouty accession is, that the supervention of the local inflammation gives relief to the constitutional disturbance, and that, having effected this, it quickly and spontaneously subsides, at least in the earlier attacks, leaving the part so lately the seat of formidable derangement, somewhat weakened indeed, but otherwise in perfect health. The dyspeptic derangements connected with gout are no doubt traceable in a great degree to the luxurious living and consequent irritation of stomach habitual with those who chiefly suffer from this disease. But this is not their sole cause, for independently of the various excitements to which the stomach is subjected, the direct effect of plethora is to induce a congestive state of the capillaries of the mucous membrane of both stomach and intestines, and an increase of its appropriate secretions,—a condition which is the fruitful parent of gastric and intestinal maladies of various kinds. In the absolute plethora of robust habits, especially when the gastro-intestinal membrane is excited by full living and stimulants, this increased secretion of mucus in the stomach and intestines is considerable, and its production is readily accounted for. The efficient cause seems to be excitement of the secretory vessels by determination of blood to the capillaries, and by the blood possessing, from the redundancy of nutritive matter, more stimulant properties; the end,—increased appropriation of the nutritive matter of the blood, and consequent relief to the overloaded circulation from that redundancy which oppresses and disturbs it.

In the less vigorous and more temperate a correspondent state arises, when from diminished appropriation of blood, through sedentary life, inactive habits, or any other cause,

the relative quantity of nutritive matter becomes greater than can be healthfully disposed of. And this serves to explain how a state of plethora and of febrile tendency so often occurs even in habits naturally spare, and where no obvious intemperance has been practised. Yet even in these the evidences of a plethoric state are readily discernible, and at an early period, if the phenomena which indicate it are rightly understood; and the effects, as displayed in the gastric and intestinal secretions, are in them even more signal than those which positive plethora usually displays, the morbid condition of the mucous membrane being generally of longer continuance and more confirmed ere attention is directed to it. These effects, though modified, are essentially the same in both, and require a similar treatment; this differing in degree only according to the different powers of the constitution so affected, and being modified only by the state of the mucous membrane, and the greater or less time during which the congestion has been suffered to endure.

If the treatment, therefore, required for the more active and simple state of disease be once established, that of the lower gradations and more complex conditions will be sufficiently apparent, differing not in kind but degree, and combined with auxiliary remedies as incidental derangements may require. In weakly habits, and where the constitution has been suffered to struggle long under unrelieved plethora, these derangements are numerous and proteiform, harassing the patient and confounding the physician. So long as they are regarded as special maladies, and treated without direct reference to the state of constitution in which they originate and by which they are upheld, the aid of medicine must be precarious and its success uncertain, conferring little benefit on the sufferer or credit on medical science. When assailed at their source by relieving the overloaded circulation, and restoring to more healthy action the several functions over which our remedies have direct and acknowledged powers, they readily give way, yielding oftentimes to the general improvement of constitution without any special means whatever being needed for their relief. To the gastric and intestinal derangements, and to those which evince disturbance of nervous function, these observations more immediately apply. Digestion is impaired, and weakness of stomach is pronounced, for which cordials and tonics are deemed the appropriate remedies. Transient relief perhaps ensues in some improvement of sensation, some increase of appetite, and thus error becomes confirmed. But, unless evacuants be adequately and discriminately combined, such remedies ever do more harm than good. Administered alone and as the chief agents of cure, they tend directly to aggravate and perpetuate disease, repressing those efforts by which the overcharged vessels would, through increased secretions, unload themselves, and ultimately establishing organic

lesions of different kinds. By continuance in their use, impression is made on the mucous membrane, diminishing its morbid secretions and thus appearing to correct them, while the stimulants conjoined impart some feelings of renewed strength. Both effects, however, are eminently delusive. By suspending increased secretion, which, rightly understood, is the direct result of a congestive state of the capillaries, and the natural means of relieving them, disease is only transferred, not removed. It may for a time quit the capillaries, or rather its character in them is altered; but it is only to be driven back on the larger vessels, where it leads to deep-seated congestions and to disorganization of various kinds. If the constitution be still entire, it is pretty sure under such circumstances to become aroused sooner or later to some febrile or inflammatory effort, for which evacuations become indispensable, and thus relief to the oppressed and overloaded organs is at length afforded; if languid or much depraved by long continuance of the morbid condition, and still more if this condition have been aggravated by abuse of cordials and stimulants, and by the neglect of evacuations, then the constitutional efforts are feeble, they are disregarded or misunderstood, and a more assiduous use of wine and sustenance is urged for nurturing that strength which such means so applied never can restore. In like manner the various nervous maladies connected with this state of constitution run a similar course. Stimulants, antispasmodics, and narcotics all lend their aid, but it is to palliate only, while in reality they do mischief. These maladies depend much on nervous sympathies arising from disordered stomach, but they are also in part owing to direct disturbance of the brain itself, through irregular circulation and morbid condition, chiefly of a congestive character, of its substance or investing membranes. Stimulants may, and oftentimes do, relieve this state for the moment, by rendering the cerebral circulation more active, and thus giving greater energy to nervous function; but the disease is not thus cured,—scarcely mitigated: the effect lasts no longer than the brief period during which the stimulus maintains its influence, and the state which ensues is still further removed from that of health. This can only be restored by so regulating the circulation that the mass of blood shall neither by its quantity nor quality cause any extraordinary excitement of the vessels which convey it, nor need any increased efforts on their part for its disposal; and afterwards by rendering such assistance to the several secretory and excretory functions as shall re-establish them in the healthy and efficient exercise of their respective offices.

In judging of the instances in which tonic and stimulant regimen is supposed to be beneficial, and which are continually adduced in proof of its propriety, it is necessary not to decide hastily or absolutely from the immediate effects, but to watch such cases to their close, when the consequences will be sufficiently

demonstrated. Many alleged cures are thus performed for which the parties have little cause to be grateful. Sooner or later formidable disease is sure to ensue, its form depending on the accidental excitements to which the body is subjected, and on the peculiar tendencies to which it is prone. In a gouty habit, reproduction of gout, and its confirmed establishment in its most aggravated shape, can hardly fail to be the result of such a regimen.

They who see much of what are termed chronic diseases must have ample opportunity of verifying by observation what is here stated. These cases present every species of internal congestion to which plethora, unrelieved by due evacuation and aggravated by stimulants, can give rise. Too often are the lesions of structure thus occasioned beyond the reach of art, while the exhaustion and attenuation are such as to preclude all attempts to relieve save by temporising palliatives. How much of this kind of evil the constitution can bear, however, and how long an oppressed and overloaded circulation may endure without annihilating all hope of relief by rational treatment, is continually exemplified. Where there is no particular tendency to local or specific disease, and the effects of plethora and of febrile action are diffused over the whole frame, they may continue for months or years, still retaining all their original character, and still admitting of valuable relief from appropriate and duly active practice. Nay, even where a special disease is engendered, if it be one of slow progress and which does not immediately affect life, it may continue for years to cause extreme distress, and yet be capable of relief from rational treatment. The following case may illustrate these several positions. A delicate female had for ten years laboured under varied and extensive disease, which from all that we could learn had been throughout of the character which we have described. Being weakly, however, and exquisitely nervous; her complaints were referred to debility, and she was pampered and stimulated with tolerable assiduity. Symptoms of general dropsy were superadded to her other complaints, and were making rapid progress when she applied to us. The character of the disease was obvious enough; the remedies were equally so; but great caution was necessary in resorting to them, both from the extreme exhaustion, and from the constitution being extensively and miserably depraved. Yet was there no alternative, for without bloodletting effectual relief could not be afforded, and from the rapid progression of disease she must have speedily sunk. We drew blood in small quantity, which was thickly buffed and cupped; purged freely, and enforced low diet. The relief was prompt: the dropsical swellings subsided, nervous maladies declined, all her feelings were improved, and even strength was increased. Blood was afterwards taken repeatedly and more freely, and she ultimately became relieved from all her complaints so far as her broken health and the ravages sustained by

long-continued disease would allow. For some years she has, in consequence of this relief, had much more enjoyment of life; and so satisfied is she of the remedy to which she is chiefly indebted, that she is herself the first to call for the lancet, when, as occasionally happens, recurring plethora or febrile action indicate its employment. This case, though not one of gout, serves to demonstrate the state of constitution which we wish to illustrate, and which is continually met with in connexion with gout; such cases, whether gout be incidental or not, require that the healthy balance of circulation and of the circulating fluid be restored, as the first requisite; and that the several secretions and excretions be corrected and promoted according as their respective derangements demand. When this is done on the principles applicable to all diseases, then may the special nature of gout receive any peculiar consideration to which it may lay claim. But so long as a plethoric state of constitution exists,—a point on which no deceptive appearances should be suffered to mislead,—and the several secretions and excretions are depraved, must all special treatment of gout by imputed specifics be subordinate to those corrective measures by which the constitutional derangements are rectified, and general health restored.

As some have cavilled at the term constitutional as thus applied, and with a subtilty of criticism more ingenious than profitable, have denied that any such thing as constitutional disease can exist, inasmuch as every morbid action must affect some part of the system, I shall here remark that I employ the term constitutional in reference to the general condition of the frame, and the collective exercise of its several functions, the due balance of which constitutes a state of health. Derangement of these functions is more or less attendant on all diseases, yet it is not always considered as forming a part of them, and is in consequence too apt to be overlooked. The general health dependent on these functions we consider as having a claim to attention in every disease, even superior to that of the special malady; it is this state to which the term constitutional is applied, and we know not how it could be so well expressed by any other. In gout it is this which is entitled to our very first consideration, for not only is constitutional derangement attendant on every accession of gout, but some degree of it is essential to the formation of the paroxysm. In proportion as gouty diathesis prevails, will greater or less degrees of constitutional derangement arouse it into activity; but some previous disorder of the general health, some antecedent disturbance in the healthy balance of functions, is necessary to this end, for without such there would be no paroxysm. On a just conception of this truth all prophylaxis must depend.

After the foregoing discussion of the nature and character of gout, we might at once proceed to the curative treatment, were it not that this essay, which is to serve for an elementary as

well as practical treatise, demands a detailed exposition of several circumstances which have not yet been noticed. For the sake both of perspicuity and brevity, we shall, in what remains, follow the order which methodic treatises on diseases usually observe.

Our general remarks on gout have been hitherto confined to those circumstances which more particularly indicate its character, and mark the morbid conditions which tend to produce it. Several others, however, require to be noticed; and here, as well as in the subsequent sections into which the subject will be divided, we shall occasionally borrow from what we have ourselves already published; and this not from indolence, but from the persuasion which we entertain, that where opinions are founded in truth, the original expression of them is more likely to be terse and correct than any repetition clothed in a different phraseology.

Dr. Cullen's definition represents gout as an hereditary disease. It is so generally, but by no means universally; and so far this character is improperly introduced into a definition. The general truth, however, of a predisposition to gout being entailed on offspring, is too well established to admit of dispute. Cases no doubt continually present themselves where no hereditary taint can be traced, manifesting that this is not essential. Dr. Scudamore, in some interesting tables, has shewn that of a given number the greater portion acknowledged no hereditary claim to the disease. The fact of hereditary disposition, however, is not thus set aside, but has been too strikingly exemplified in numberless instances to be easily shaken. From the very slight influence which this point has either on pathology or practice, it is, in truth, of little real importance. The only consequence of admitting such predisposition seems to be, that when it is supposed to exist, gout may be expected to take place under circumstances which, independently of this tendency, would not have power to originate it; and that hence a salutary caution may be suggested to those who have any consciousness of hereditary claim, to guard with particular care against the various causes which excite gouty action. While false theory prevailed, and the establishment of gout in the extremities was considered essentially desirable as relieving the constitution from peccant humours supposed to be thrown on the affected joint; and when the suspicion of a gouty diathesis led to a free use of stimulants as a means of repelling the enemy from vital parts; then the supposition of hereditary taint was not harmless, the regimen enjoined tending directly to arouse what might have lain dormant, if not to create what might otherwise never have existed. But if rational principles of gout, its nature and treatment, were generally established, the admission of its being hereditary could lead to nothing but good, and might effect such changes as would in time cause the evidences of hereditary disposition wholly to disappear. Indeed it would be well if the fact of hereditary transmission

were more generally received and more deeply impressed, as many who would prefer the liability to gout to any sacrifice of luxurious indulgences, so long as they regarded the choice as affecting their own persons alone, might exercise some self-restraint if assured of the consequences which their excesses might entail on their offspring and descendants.

Though the paroxysm of gout usually occurs in the way described, and without any evident external cause, yet any accident or injury of a joint occurring in a gouty subject, may, instead of simple inflammation, bring on a fit of gout, or rather the local inflammation excited may assume all the characteristics of that disease.

The precedence of gastric derangement is not necessary to constitute gout, many being unconscious of any such up to the accession of the local inflammation. In advanced cases, however, and in broken constitutions, this premonitory indication is rarely absent.

Pyrexia so generally attends that it may well be considered a characteristic feature. In those cases where, from languid or enfeebled powers, it is less obvious, and where to superficial observation it might appear not to exist, more careful investigation of symptoms would rarely fail to detect it.

Women, though not exempt from gout, are less subject to it than men. Dr. Gregory used to state the proportion as one to fifty in England, one to one hundred in Scotland. For this relative immunity in females they seem indebted to their greater temperance, and also to the facilities which the female constitution possesses of throwing off redundancies by natural outlets. Dr. Gregory had observed among his patients, that the women who suffered from gout had antecedently been subject to profuse hemorrhages, such persons being generally plethoric through indolence, sedentary lives, and high feeding, and hence predisposed.

Vigorous and robust constitutions are most subject to gout, though no spareness of habit affords security against it. The cholero-sanguine temperament is said to be that which is most liable.

Gout is most generally a disease of middle and advanced life. Its attacks usually occur from the age of thirty-five onwards. When the predisposition is strong, however, it may commence much earlier. Dr. Gregory met with it oftentimes among his pupils, young men from 18 to 22, and who had not earned it by intemperance.

The relief to the general health imputed to the superpervention of the paroxysm, though an observation partially founded on truth, becomes progressively less speedy and less signal as the disease advances. It has ever been too much relied on, and has led to much pernicious practice, both medicinal and dietetic.

So many causes, both remote and immediate, have been assigned to gout, that they require to be noticed; for though most of them are merely contingent and accessory, they all merit attention where regard to the juvenia and lædientia is so important.

Hereditary disposition has been sufficiently discussed, as have also the influences of plethora and of the unascertained cause from which gout derives its distinctive character. Whatever induces a state of plethora may become a cause of gout, whence luxurious living, indolence, and sedentary habits, have ever been the chief means of exciting or producing it. By these is the gouty predisposition urged on to active disease; and, so far as our knowledge extends, they are fully capable of originally producing it. The extremes of luxury or of indolence, however, are not required to produce this effect. Lesser degrees may induce plethora sufficient to destroy the balance of health, and thus beget disease. A slight redundancy of nutritive matter in the blood, whether arising from excessive supply or diminished expenditure, may create an inflammatory state, which, in a habit predisposed, may lead to gout, even where the habits of living may appear temperate, and where moderate exercise is taken. No terms are more loose in their general application than temperance and exercise. Credit is continually claimed for the former, where the animal food and wine habitually taken far exceed what nature requires or can bear; and the name of exercise is oftentimes given to bodily exertions so gentle that they lead to no increased expenditure of blood, while, by increasing appetite, they too often tend to augment and enrich it. Gout is a disease of the rich and indolent, not of the poor and laborious; and this truth, so obvious and incontrovertible, ought to have had more influence on medical opinions than it has been allowed to exercise. If there were no other fact whatever ascertained, this alone might suffice to point the way to the efficient prevention and treatment of gout. In Scotland there is an old saying worthy of being held in remembrance, that any man may free himself from gout by working for and living on sixpence a-day.

Next to plethora, whatever causes induce debility of stomach have been regarded as principally influential in bringing on gout. The observation is to a certain extent true; yet the facts on which it rests have been egregiously misconceived, and much pernicious practice has in consequence resulted. Weakness of stomach being assumed, tonic and invigorating regimen were of course considered as indicated, and long and pertinaciously has its use been persisted in, notwithstanding the utter failure of such treatment to mitigate, much less subdue the disease. Had the nature of this assumed debility of stomach been more closely investigated, it would have been seen to present a character very different from what tonic or stimulant remedies could essentially relieve. It might, at least in the earlier stages, have been directly traced back consecutively to inordinate and depraved secretions, turgid condition of the mucous membrane, congestion of the capillaries, and general plethora, all readily relieviable at the commencement by evacuations and abstinence, all aggravated by nutritive diet, stimulants, and tonics. All reference, therefore, to debility of stomach as a cause of gout should

extend, not merely to the alleged weakness, but to the several causes, both coincident and consecutive, by which the important function of digestion becomes weakened or disturbed.

Various causes are instrumental in exciting the paroxysm, but they are all subordinate to those mentioned, and incapable of such effect unless where depravation of health has prepared the way. Excess of venery is an acknowledged exciting cause, as is also abuse of spirituous liquors, as well as indigestion, whether occasioned by the quantity or quality of the food taken. To the immediate effects of this last cause may be referred many cases of imputed gout in the stomach, which have been wholly independent of gout. Dr. Gregory used to relate a case where he was called to a patient said to have been seized with gout in the stomach; but he found his complaint caused, not by gout in the stomach, but by pork in the stomach, of which difficultly digestible food he had too liberally partaken. By getting rid of it he was perfectly relieved, and there was nothing more heard of gout for that time.

Intense study has brought on gout. It is stated by Sydenham that one of his most severe attacks was occasioned by immoderate application in writing his essays on the disease, and that gout returned as often as he attempted to go on with the work.

Purging has been said to bring on the paroxysm, and such a coincidence no doubt occurs; but it would be a great error to suffer this observation to deter from a judicious use of purgative remedies.

Continued costiveness is a more probable cause, yet this can only be regarded as an incidental derangement, depraving, so long as it continues, several other functions, and adding to the disorder of the general health.

Change from activity to indolence has been often noticed as leading to gout, a circumstance readily understood. Change from low living to high is equally intelligible. But sudden change of the opposite kind has been marked by the same effects, as was signally exemplified in the patients of the celebrated Dr. Cheyne. He, as all know, was the advocate of temperance, and having enjoined it to his gouty patients rather too absolutely, and without sufficient discrimination, he had the mortification to find that his directions, so far from obviating the attack, hastened the paroxysm, which afforded great exultation to the opponents of his doctrines. Their triumph, however, was far from complete, although it served for a while to confirm existing prejudices.

The hypothesis of gout being caused by a special morbid matter, eliminated and expelled by means of the paroxysm, has been fully and ably refuted by Dr. Cullen. There is no proof whatever of any such existing; and assuredly it is not, as was long imagined, identical with the concretions deposited in gouty joints.

Cold, heat, external injury, depressing passions, too great exercise, especially in walking, have all been enumerated among the causes capable of exciting gout; but they can only be

regarded as mere accidents, having no power to induce the disease, save when the habit is on the very verge of the paroxysm.

The diagnosis of gout must be derived from its history and general character, for there is no pathognomonic symptom whatever to distinguish it from rheumatism, the only disease with which it is liable to be confounded. Each disease, perfectly formed, is sufficiently distinct from the other; but the intermediate degrees approach each other so nearly, that to discriminate with absolute certainty would require a more intimate acquaintance with the essence of both diseases than we can take credit for possessing. All that can be done here, then, is to note the peculiarities of each, and then to leave it to the practitioner's own judgment and observation to decide to which any equivocal case may belong.

Gout is generally a disease of advanced life, not occurring for the most part till thirty-five; rheumatism most frequently attacks the young, that is, from the age of eighteen to thirty. Yet the converse of this is so often true, that the observation furnishes no ground of accurate diagnosis; rheumatism attacking every age, while, as has been shewn, not even childhood is exempt from gout. Gout in its earlier attacks fixes on one joint, extending not beyond; rheumatism, even on its first seizure, most generally involves several. Gout, while simple and incipient, runs a definite course, the local inflammation spontaneously and completely subsiding in a few days; rheumatism has less tendency to spontaneous decline, and, unless arrested by prompt and active treatment, usually continues much longer. The subsidence, however, of local inflammation in rheumatism under active treatment resembles very closely the natural abatement of gout. In gout the constitutional disturbance sensibly abates on the supervention of the local inflammation; this does not appear to be the case in rheumatism, where, on the contrary, the articular inflammation is often attended with increase of fever. In gout the part inflamed is red, tense, shining in a high degree; in rheumatism it is less so in all these respects. Desquamation of the cuticle has been regarded as a criterion of gout; but the cuticle is oftentimes detached in rheumatism much more extensively than ever occurs in gout. We have seen the cuticle so completely separated from the hand and wrist in rheumatism as to admit of being drawn off like a glove. In gout the pain is exquisite, even when the part affected is at perfect rest; in rheumatism it is much more moderate when the part is at rest, though most acute on the slightest motion. Gout is more apt to be preceded by gastric derangement than rheumatism. After all that can be said on the subject of diagnosis, much uncertainty must still attach to many instances, while there are modifications which partake so much of both, that it would be impossible to assign them with certainty to either; and accordingly we find the term rheumatic gout, though not recognised by nosologists, in familiar use among the vulgar, and not scorned even by practitioners. Are we

yet prepared to decide to which the very peculiar disease known among medical men as nodosity of the joints belongs? It is usually classed with rheumatism, yet are there quite as many grounds for allying it to gout. After all, the distinction is of little real importance, for if the pathology of gout, which we believe to be true, be established, the treatment of the individual case will not be very different to whichever genus of disease it may be assigned.

The prognosis of gout must depend on so many circumstances, that it would be impossible to affirm it positively or with any precision. Simple gout occurring for the first time runs a determinate course, ending generally in health, and cannot therefore be regarded as a disease of much danger; on the contrary, it has, by a strange delusion, been customary to hail its presence as conservative of health and a guarantee for longevity! However the supervention of the paroxysm may occasionally obviate greater evils, we should greatly doubt the desirableness of its occurrence, and must leave it to gouty sufferers to appreciate both the value of the remedy and the enjoyment of the years so prolonged. In advanced gout the state of constitution, the ravages already sustained, the organs incidentally affected, and even the principles on which the treatment of the particular case is conducted, must be taken into account ere any conception either of the probable duration or event can be formed.

It has been customary to represent gout as incurable, and for ages it has been pronounced the opprobrium of medical science. Ere proceeding to discuss the treatment, it may be worth while to consider how far this reproach has been justly attached. Whether there be or not a cure for gout, is a question of which the answer must depend on the sense in which the term cure is used. It is a common error to contemplate diseases as if each, instead of consisting of an aggregate of functional disturbances, were itself something individual and specific,—some element superadded to the frame producing a specific derangement of health, and capable of being corrected or neutralized by its proper remedy, as a poison by its antidote. Thus the doctrine of specifics has ever prevailed, and it continues to hold its ground even at the present day. It has even been imagined that as mercury is an imputed specific for syphilis, cinchona bark for intermittent fever, there must for every disease exist in nature some peculiar and appropriate remedy which it is the business of physicians to discover. No disease has been more signally subjected to this misconception than gout, and the search for a specific capable of extinguishing it has been often and anxiously renewed. To those who thus judge of diseases and their treatment, it may be confidently replied that there is in medicine no cure for gout, for no remedy capable of realising such expectation ever has been discovered, or ever can be. To such delusion gouty sufferers are peculiarly inclined, for, habituated for the most part to luxurious indulgences, and reluctant to forego them, they lend a willing ear to every

vain boast which affects to cure them without a sacrifice of their sensual enjoyments. The consequences of this error have been doubly injurious, not only by diverting attention from that investigation of the disease which could alone explore its real nature and devise its proper treatment, but also, where any remedy of peculiar efficacy was happily discovered, by causing such indiscriminate application as to render it in the end more injurious than serviceable, and at length to destroy the reputation to which it might justly lay claim. But if gout be regarded as it really is, an assemblage of functional derangements, traceable respectively to intelligible causes, and, when rightly understood, admitting of correction by suitable agency, then, though there be a superadded cause in the essential principle of gout, of the precise and intimate nature of which we are still ignorant, the disease may be pronounced curable in the same sense in which we apply the term to other maladies, provided practitioners, instead of vainly seeking for specifics, pursue the course of treatment which true medical science enjoins, and patients be content to follow that regimen by which alone the end can ever be attained. By medicine alone we can do little to obviate the predisposition which leads to gout; but by suitable regimen duly and inflexibly persevered in, we may render it harmless, so that even in cases of high susceptibility, where, notwithstanding our best care, paroxysms may occasionally recur, these will be slight, and productive of but little evil. But even this liability, if manifested in the earlier periods, should be regarded as owing to some imperfection in the use of preventive means; for if these be fully and judiciously employed, the renewal of paroxysms may, as long as the general constitution is still uninjured, be wholly and effectually prevented.

This assertion, as now expressed, is of course limited to those cases where gout on its first accession is subjected to proper discipline both remedial and prophylactic; for where the predisposition is strengthened by repeated accessions of the disease, and disorganizations have taken place in the joints, or any of the viscera have, through the effects of gout, become depraved, the hopes of complete success must be proportionally weakened. In this sense, then, it may be boldly averred that gout is not an incurable disease. We can cure the paroxysm, and can restore the patient to perfect health, which it is in his own power afterwards to preserve; and if he, in defiance of right counsel, renews the disease by continuing the luxurious and indolent habits which foster it, the reproach should lie, not on medical science, the precepts of which he disregards, but on his own weakness and wilful perseverance in injurious practices. Other diseases as well as gout, nay all, are liable to recur on the predisposing and exciting causes becoming renewed; yet they are not thence considered incurable, nor are they deemed a reproach to medical science merely because medicine alone cannot secure against relapse.

There is no reason why relapse of gout should not be equally referred to a renewal of the causes which lead to it, and as the principal of these are obvious and capable both of prevention and correction, the incurableness of gout should not be alleged so long as the means of cure are neglected or inadequately employed, nor should medical science be reproached when its clearest dictates are discredited, and its most urgent remonstrances unheeded and despised.

The most important treatment of gout is the preventive; for if this, however successfully the paroxysm may be relieved, be not assiduously pursued, disease will recur, and acquiring force by repetition, will eventually inflict all its wonted penalties. The principles, too, of the preventive treatment are the same which should govern the practice through all stages and conditions of the disease, modified only by contingent circumstances, but never superseded nor reversed; on which account a full discussion should be given in the first instance to the prophylaxis of gout.

If the views exhibited in the foregoing pages be not wholly fallacious, the establishment of a rational and efficient prophylaxis of gout can be neither difficult nor doubtful. It has been seen that to constitute gout two circumstances must concur,—a predisposition to this form of disease, and a loss of balance in the constitution through excess of nutritive matter, creating what is termed plethora, and arousing the predisposition into active disease. It would be useless to dwell on, or affect accuracy in deciding which of these conditions is the more active, which the more passive,—which should be called the predisposing cause, which the exciting. The main point to consider is, that their concurrence is essential; for if there be no tendency to gout, plethora may induce any other form of local inflammation or fever, but will not give rise to gout; if there be no plethora, even a strong hereditary disposition may lie dormant, and the elements of gout, of whatever nature they be, will not shew themselves by the formation of a paroxysm. Of these causes one is utterly unknown to us, and consequently we are unprovided with any positive or direct means of acting on it; but the other is completely under our controul, and however great the tendency to it in any instance, we have ample power when it does arise to remove it by means of depletion and abstinence, and to prevent its recurrence so as with certainty to keep within the bounds of health by temperance and exercise. To these few and simple instruments of prevention may be referred all the procedures required for prophylaxis; all further discussion of which must consist of pointing out the degree in which they may be severally required, and the modifications necessary in applying them so as to attain the end desired without hazarding other evils, to obviate redundancy of nutrition without withholding adequate sustenance; to repress hypersthenic orgasm without inducing asthenic debility; and, in averting an inflammatory dis-

ease, not to beget others of an opposite character, but to preserve the constitution in that due exercise of all its functions which perfect health implies and requires.

Though the instances may not be many of gout being eradicated or kept quiescent by means of regimen, inasmuch as gouty subjects have been at all times singularly averse to pursuing such discipline, yet have they been quite sufficient to establish the fact of the capability; and it should be borne in mind that by no other means has the end ever been attained. The late Dr. James Gregory of Edinburgh was a signal instance of the perfect success of the regimen which he ably advocated and strenuously enforced. With a strong hereditary predisposition, gout having existed in his family for generations, and his father having been an early victim of it, he was himself seized with the disease at a very early age; but subduing it by abstemious living, he was disposed to congratulate himself on having obtained exemption. The effects, however, of slight indulgence during a casual visit to Oxford, admonished him that he could take no liberties; and from that period he abided steadily by the regimen which he had laid down for himself, the safety and efficacy of which he had proved, and by adhering to which he was never afterwards visited with gout. This account of himself he used to deliver annually to his class; and when the writer of this article heard him do so in the sessions of 1802 and of 1803, he had reached his fiftieth year without experiencing a return.

In instancing his own case, Dr. Gregory's object was not so much to adduce proof of the efficacy of preventive regimen as to show that the very spare living and bodily labour which some had inculcated, and which deterred many from attempting to pursue a rational course, were by no means requisite; but that a very moderate degree of both would, if persevered in with steadiness, fully suffice. He was accustomed to appeal, in proof of this, to his own person, the robust form and fresh complexion of which gave ample assurance of its being sufficiently nourished, and to conclude his remarks with saying, "You will allow, gentlemen, that I am no starveling."

The consideration of preventive regimen may be conveniently subdivided under two heads,—the prevention of plethora, and its removal whenever its appropriate phenomena denote its presence. For the first, it would be impossible to lay down any express rule of diet that would be suitable for all habits and constitutions; and to this head all the doctrines advanced in the article PLETHORA apply. Where there is a predisposition to gout, with a tendency to fulness of habit, great care should be taken not to minister to fulness by too much or too nutritive diet. Animal food should be sparingly taken, and fermented liquors should be cautiously avoided. The quantity of food necessary for full health and strength is very moderate, especially where bodily exertion is inconsiderable; and the majority of mankind

consume habitually far more than is good for them; whence arises a large portion of their diseases. The doctrine is unpalatable, and the physician who enforces it will hardly be a favourite with the many; but it is not the less sound; and so long as mankind persist in closing their eyes to the truth, they must suffer the consequences of their wilful blindness. When the time arrives, as come it must, that a knowledge of the animal economy shall form a part of liberal education, and each individual shall be capable of comprehending the structure and functions of his own frame, such truths will be more readily acknowledged, and physicians will have fewer obstacles to contend with in the conscientious discharge of their duties. The temperance necessary for lessening the tendency to gout has been often and ably enforced; yet, judging from the ravages daily witnessed, and from the accounts of early treatment and of regimen pursued which such sufferers report, but little progress has yet been made in establishing generally sound principles of management for gouty subjects. Nutrition is still encouraged as a means of supporting strength, wine is enjoined to keep gout from the stomach, and excesses of every kind are committed; while credit is taken for moderation merely because they are not carried to extreme, nor as far as inclination might prompt. Whatever is taken beyond what the wants of nature demand is excess; and numbers are guilty of it who are unconscious of being so. In a healthy frame the natural energies are ever active in appropriating and throwing off the redundancies, and in this way apparent health may be long preserved; but if the excess be continued, disease is sure sooner or later to result, when medical discipline, now indispensable, carries off, by one outlet or other, what the constitution can no longer endure. It is the part of wisdom to avoid this issue by maintaining habitual temperance, the practice of which will ever ensure a rich reward.

Dr. Cullen has judiciously laid down as indications of treatment in gout, to moderate the paroxysm, and to prevent its recurrence. The practice of many gouty sufferers seems exactly the reverse, namely, to hasten the paroxysm and to increase its violence, under the false impression that a severe attack eliminates and expels from the system more gouty matter than a weak one. The doctrine claims to be founded on fact and experience, yet is it eminently untrue. The fact that the accession of gouty inflammation brings relief to pre-existing constitutional derangement belongs only to the earlier seizures, and does not hold true generally of gout; and the belief of the paroxysm purifying the constitution of gouty matter in proportion to its violence resulted entirely from a false hypothesis respecting the *materies morbi* of gout, and though supported by the high authority of Sydenham, is utterly untenable. There can be no doubt at the present day, that the indications of Cullen are those which ought to be followed.

Next in importance to regulating the ingesta,

is preserving a state of free and adequate excretion. However moderate the diet, if through neglect of exercise or other causes nutritive matter be imperfectly appropriated, and excretions become defective, a loss of balance must result; the blood must become charged with both nutrient and excrementitious matter in excessive proportion, decline of health ensue, febrile excitement become aroused; and in a gouty habit such progressive depravation will be pretty sure to end either in a paroxysm, or in an abortive effort of the constitution to form one. These are the cases which have involved the subject of gout in so much obscurity, and by their equivocal character have led to the abuse of stimulant treatment. It is obvious that the state of constitution here referred to may be relieved in two ways, apparently opposite; either by exciting the constitutional powers to increased efforts for appropriating and expelling the redundant matter, or by diminishing this so as to keep it within the ordinary powers of nutrient action and excretion. On a fair comparison and just estimate of the relative value of the two modes, there can be little room for hesitation in giving a decided preference to the latter. Far better is it to prevent plethora by temperance in diet, and to promote appropriation and excretion by exercise, than to keep the energies of the frame overstrained by continued use of stimulants. The superiority would be great were we to regard only the general ill effects of continued excitement, which not only exhausts power, but creates a necessity for the stimulus to be progressively increased; it becomes far more so when we take into account the destructive lesions of important organs, to which stimulation of overcharged vessels almost necessarily gives rise. If plethora be obviated by temperance and exercise, or removed by depletion and abstinence, the several organs and functions of the frame are left in their natural and healthy state, in which the natural powers, unaided by stimulants or tonics, are fully capable of preserving them. But when it is attempted to remedy plethoric ills by increasing the energies which nature exerts for their removal, the several functions, even when successful in effecting temporary amendment, become exhausted and debilitated, their ordinary efficiency is impaired, congestions ensue, leading to local inflammation and organic lesions; and a host of maladies severe and untractable are the eventual result. By rational prophylaxis all such consequences may be effectually and certainly prevented, while daily observation too clearly shows how little they gain who combat such ills by stimulants and tonics. So long as temperance is observed, the several functions of health will be so performed as to need little assistance from art. Still, as no casual care may suffice to give full security against casual derangements, attention should be given to the several excretions, the most important of which are those of the bowels and the skin. The bowels should be kept free, and the skin perspirable; mild

aperients will serve the former purpose, active exercise the latter.

After temperance in diet, and adequate excretions, the next agency available for obviating plethora by promoting the appropriation and final expulsion of what is taken into the system is exercise, which in the prophylaxis of gout is of the highest importance. However complete and undeviating the temperance which a person threatened with gout, and anxious to avert it, may observe, the aid of active exercise will still be necessary to give the security which he seeks, and which his case admits of. Indolence in him may beget evils directly analogous to those which repletion produces, and, though modified by circumstances, leading to similar results. Whatever the sustenance taken, it requires to be expended in all of its several appropriations; and the effete matter which it continually displaces needs to be discharged from the system by active and adequate excretion. If nutritive appropriation fail in healthful energy in any of the tissues of the frame; if, through defective excretion, the effete matter continually passing through the appropriate outlets be not fully thrown off, both nutritive and excrementitious matter must accumulate in the blood in undue proportion, and induce a condition of the body generative of disease. To promote both purposes, adequate exercise is the natural agent, the use of which cannot be superseded by any medicines however valuable or however lauded. Blood-letting may remove redundant nutritive matter from the circulation; purgatives, diaphoretics, and other evacuants may succeed in rendering the excretions more active and efficient; but no sound mind, judging even by common sense, much less if at all aware of the relative effects of preventive and remedial courses of procedure, can hesitate which to prefer. It is much better not to overflow than to be obliged to empty; it is far more healthful to prevent accumulations of excrementitious matter through active exercise, for which the body is so admirably constituted by nature, than to remove them by any evacuants, however certain in their operation. The two simple terms then, temperance and exercise, convey whatever is essential in the prophylaxis of gout; and, if rightly understood so as to be strictly practised, they would be amply sufficient for all useful guidance. Further discussion could only regard the degree to which each should be carried so as to ensure its good effects without hazarding contingent evil. To pursue the subject minutely in this place would swell this article beyond its allotted extent. They who comprehend the doctrines advanced, and imbibe their spirit, will be at no loss so to regulate regimen as to produce nothing but good. It may be remarked that extremes in either respect are quite unnecessary; and the evidence of Dr. Gregory's personal experience has sufficiently shown that gout may be thus effectually prevented without extraordinary macilency, or any privations incompatible with rational enjoyment of life.

But notwithstanding all the care which the most cautious can take, irregularities of diet, interrupted exercise, and other inevitable deviations from the prescribed course, will induce occasional plethora leading to derangement of health. The evidences of this, and the means of abating it, become then the next subject of consideration. When fulness of habit begins to appear, the diet, however moderate, should be still further abridged; animal food should be more sparingly taken, fermented liquors discontinued, the bowels kept more free, and the exercise rendered more effective; and these attentions would be expedient even while the increasing fulness presented no evidences but those of health. Should they suffice, nothing more will be needed. But if plethora advance so as not to be thus removed, if consciousness of health becomes disturbed by morbid feelings, and these be accompanied by a labouring circulation; if, finally, a hot skin, quick pulse, and white tongue, denote the stage of febrile action to have commenced, then, though no local congestion or inflammation should yet have occurred, blood should be taken, purgatives employed, and the whole regimen should be strictly antiphlogistic. It may be deemed that at this incipient stage bloodletting may be dispensed with, and certainly it is not the general practice so to employ it; but this we attribute to practitioners not being sufficiently aware of the real state of constitution, nor of the great advantages derivable from early bleeding. It is true that this stage is not immediately dangerous; that it may be suffered to advance somewhat without much hazard, it being the consecutive derangements rather than the incipient plethora or febrile action which beget danger; that it may even get well, and without ulterior mischief, although bloodletting be not practised. But these admissions will not alter the question either of the real nature and tendencies of plethora, or of the remedies which most safely, promptly, and effectually relieve it. Of these remedies the most direct, and unquestionably the most eligible, is bloodletting. It removes the cause of disease more effectually than any other remedy; it more promptly restores to the several functions the healthful energies of which plethora with its consequences deprives them; it supersedes the protracted use of other evacuants; and by quickly suspending the exhausting effects of continued febrile action, it virtually preserves strength instead of wasting it. For this purpose large or repeated bleedings are never needed. A single venesection to twelve ounces, with purging and low diet, will oftentimes suffice to arrest progressive disease, and re-establish the sanative efficiency of the natural powers. And here, again, early bloodletting saves even blood, if this were an object, (and it is an object that it should never be unnecessarily nor superfluously taken;) for moderate bleeding early employed will avert severity of disease, which, where it does ensue, often demands profuse depletion to save life, and thus consigns to tedious convalescence, if the party be fortunate enough to escape a more fatal

result. It might be beneficially laid down as an axiom, that, abstractedly, bloodletting is the direct remedy of febrile action, its use and modifications being determined by circumstances. In idiopathic fevers produced by miasmata, and attended with prostration of power, its employment may be questionable, and great caution at least is required in applying it; yet when early and judiciously employed, it has proved a powerful agent in arresting the progress and mitigating the symptoms even of typhus, as the records of medicine abundantly prove. In such cases much requires to be taken into account, which the skilful practitioner will not overlook; and especially the character and tendencies of the prevailing epidemic should be allowed their full influence on his judgment. In febrile action of an ordinary character the same caution is not necessary; and here the solicitude should be not to escape bloodletting, but to discover sufficient evidences of a labouring and disturbed circulation to encourage the having recourse to it; for when timely used, the duration of disease is materially shortened, the necessity of medical discipline considerably diminished, while the constitution is spared the ravages which protracted fever, even when ultimately cured, too often entails. With these remarks on the means of preventing plethora in a healthy subject, and of remedying it when it does occur, we may now dismiss the prophylaxis of gout.

From all that has been stated in the foregoing pages of the nature and character of gout, it is obvious that antiphlogistic treatment is that which is essentially required for its cure; and were it not for the complications produced by false theories, improper regimen, and the perverted use of remedies, the establishment of this truth might almost suffice for all practical guidance. When the prophylaxis of gout shall be more clearly understood and more generally practised, these complications will decline, and simple treatment will alone be needed. But until that happy day shall arrive, it must be necessary to specify the various practice required, so as to mark its adaptation to the several varieties of constitution, stages of disease, and morbid complications, which are sure to present themselves for a long time to come. On the practical instructions which follow we wish to observe, that, however they may seem to flow from the principles laid down, they have not resulted from merely speculative views, but are supported by the best experience of the profession, as handed down by distinguished writers for ages, and are established to our own firm conviction by all that we have ever seen of the disease or its treatment.

A first attack of gout affords, of course, no opportunity for prophylactic treatment. It comes on, if not unannounced, at least unexpectedly, the party being first warned of it by the actual seizure. The treatment of the paroxysm, therefore, in its simplest state, becomes the first subject of practical illustration. There can be no doubt that the more this is treated

on general principles, and the less the special nature of the disease is heeded, the more prompt and effectual will be the relief given, and the more perfect the correction of that morbid condition of the system in which the attack has its origin. If there be a full habit, with active fever, as marked by a full and frequent pulse, hot skin, and white or loaded tongue, then bloodletting, purging, and antiphlogistic treatment should be employed as freely as if the fever and local inflammation passed under any other name. In mild attacks and where constitutional disturbance is less strongly marked, such active treatment may, perhaps, be waived, and the tendency to spontaneous subsidence already noticed, be trusted to without immediate ill consequence resulting, especially if, after this admonition, a prophylactic regimen be steadily pursued. Still, however mild the attack, except it take place in a broken constitution, or under circumstances decidedly adverse to direct depletion, we would deem it wise practice to take some blood, so as to render more complete the purposes for which nature institutes the paroxysm. Of this treatment of a first paroxysm we certainly cannot adduce cases; but as in more advanced gout we have bled freely, both on the approach of the paroxysm, at its height, and on its decline, regarding only the state of constitution, and not the special malady, and this not only with perfect safety, but with eminent advantage, we feel fully justified in applying to a first attack of gout the principles which we would not hesitate to follow at later periods, and under circumstances less favourable to their full and beneficial operation. It has been seen that the simple paroxysm runs a definite course, terminating in a few days in renewed health. And if the gouty effort be slight, and the existing plethora inconsiderable, this alleged restoration of health may be so complete as to need no interference from medicine. But if there be much plethora, then the fever aroused may not subside on the gouty nîsus having effected its purpose of establishing a local inflammation. The pulse may remain high, the skin hot, the tongue loaded, with the various other depravations usually attendant on a febrile state. Under these circumstances no question can arise on the propriety of effecting by art what nature fails to accomplish. Bleeding, purging, cooling salines, with antimony, and low diet, should all be employed in proportion to the acuteness of the symptoms, and the constitutional energies displayed. But whatever hesitation there might be in interfering with a first paroxysm, on the ground of its not being needed, and of nature being equal to accomplishing her purpose, there can be none, when the disease recurs in a constitution otherwise healthy and vigorous, in resorting to the same constitutional treatment which would be applicable in any other active inflammation. The plethora and inflammatory action are abundantly demonstrated by the attendant symptoms, there being a full, strong, bounding pulse, with hot skin, white tongue, and all the concomitants of

active fever. The local inflammation, so far from militating against the employment of active practice, affords additional reason for promptly resorting to it; for if not speedily allayed by suitable depletion, severe pain is unnecessarily prolonged, disorganization is hazarded, and greater debility of parts ensues, with more impeded motion of joints, and more tedious convalescence. On the accession, therefore, of the paroxysm in an otherwise healthy subject, if no earlier opportunity be afforded, a full bloodletting should be employed, and the bowels should be freely purged with a competent dose of calomel and colocyath, followed by a saline cathartic. If these means succeed in making impression on the system so as to reduce the pulse nearly to the healthy standard, the general fever may be treated by saline antimonials and aperients, like any other febrile excitement. Should the pulse again rise in frequency, force, or hardness, with renewed heat of skin and whiteness of tongue, the bleeding and purging would require to be repeated. The only distinction which we know between such an attack and any of the simple phlegmasiæ, regards the topical applications; for so long as the local inflammation is removable by constitutional treatment, topical remedies should not be employed, unless demanded by an urgency of suffering, such as, when constitutional treatment is properly employed, will very rarely occur. The local inflammation has a natural tendency to subside, as has been stated; and it is perfectly justifiable to await this, at least for the usual period, without resorting to topical remedies. When it lingers, the fault lies not in the joint, but in the constitutional state, which keeps up the inflammation, and to this state are remedies best directed.

There is a distinction, both in the febrile state and local inflammation, that deserves to be noticed. Both to a certain extent belong to the paroxysm, constituting it and subsiding with it; but both may continue beyond the time when the paroxysm, running its natural course, would spontaneously subside; and this is dependent, not on the gouty nîsus, but on the constitutional condition. Relieving this condition by depletion and febrifuge regimen will subdue disease in both respects. If the local inflammation, however, have been suffered to establish itself, it may keep its ground even after the plethora and febrile action have been sufficiently abated; and here it is that local treatment may be needed for expediting and completing the relief of the inflamed joints, and averting these structural lesions which protracted inflammation is sure to occasion. To abstract blood locally before the general circulation is sufficiently unloaded, gives no effectual relief; for if the constitutional state be not corrected, the local inflammation, however it may be allayed by topical bleeding or cooling applications, is pretty sure to recur, while some risk is incurred of the inflammation being transferred to some other joint, if not to some vital organ. Leeches, therefore, though their use is sanctioned by high authority,

should assuredly not be employed in the ordinary treatment of the paroxysm, nor until the continuance of local inflammation after the removal of the constitutional disturbance manifests that the local disease has acquired an independent existence. In this state leeches and other local remedies may be safely and beneficially applied, but antecedently to it their use is not appropriate. If leeches be unsuited for what may be strictly regarded as the paroxysm, repellent applications are still more so; and though in slight cases they may appear to succeed, their use as a general remedy for gout is eminently hazardous. If the constitutional treatment be conducted as it ought, they will be rarely needed; and far better is it that the local inflammation should yield to the constitutional correction, than that it should subside under local remedies. In the one case its decline affords evidence that radical relief is obtained, an assurance which must be incomplete when topical treatment is trusted to, however successful it may in any particular instance prove. That the final cause of a gouty paroxysm is the relief of the system, and that it accomplishes this to a certain extent, are truths sufficiently established; and if the relief were complete, the interference of art would be superfluous and improper. But there is strong reason for believing that the paroxysm does not sufficiently relieve the surcharged system; and hence the assistance of art becomes necessary for seconding the operations of nature. But this assistance requires to be directed to the constitutional state rather than to the local ailment. So much is effected by the gouty effort, whatever its intimate nature may be, that it would be unwise to interfere with it otherwise than by removing the necessity which incites it. This may always be safely done by abating plethora and restoring general health; but until this precaution be taken, it cannot be expedient nor always safe to arrest suddenly the local malady by local bloodletting or repellent applications. As subsidiary to the constitutional treatment, there can be no objection, in highly nervous temperaments, and where inordinate sensibility prevails, to sooth by cold or tepid sponging, or by any equally harmless adjuvant; but as was before remarked, if the constitutional treatment be adequately employed, such remedies as these will be little needed. In treating the paroxysm of gout, the indications are to relieve the constitution, and to moderate the local inflammation, so as to prevent the disorganization to which its violence or continuance would give rise. Both are best fulfilled by the constitutional treatment already directed. The converse of this practice, or that which, disregarding the constitutional derangement, directs its efforts to subduing the local inflammation by any means capable of producing such effect, has been at times confidently advised, and was revived with high commendations some years ago, but no treatment can be more hazardous nor more at variance with sound pathology. By promptly relieving the paroxysm through means of constitutional treatment, suffering is abridged,

danger averted, convalescence accelerated and rendered more perfect, the recurrence of disease obviated so as to be thoroughly capable of prevention by prophylactic regimen, and at least rendered more distant; and the gouty diathesis, which the long continuance and repetition of paroxysms invariably strengthen, is weakened and suspended. Were incipient gout always treated on these principles, and the premonitory signs which give notice of its recurrence detected in sufficient time to employ the depletion and abstinence necessary for averting the paroxysm; and were prophylactic treatment afterwards pursued to the extent and with the steadiness necessary for ensuring its effects, the victims of reiterated gout would be few, and the disease would soon cease to be the opprobrium medicorum which it has been so long considered.

It must be borne in mind that the foregoing remarks and practical instructions apply to gout as occurring in its simplest form, and in a constitution otherwise healthy and of unimpaired vigour. When it arises in a habit naturally feeble, vitiated by other diseases, or injured by repeated accessions of gout itself, the treatment, though similar in principle, must yet be greatly modified; and on the accuracy with which the necessary measures of relief are adapted to the existing powers, and suited to the concomitant derangements of function or structure, will the ultimate success depend. The perfect health of each and every function should be the standard by which all deviations should be judged; and the endeavour should be to restore severally, and by the treatment appropriate to each, whatever may appear disordered. Far preferable is this simple and intelligible proceeding to regarding any symptom as characteristic of gout, and applying to it some supposed specific, without reference to the direct operation of the remedy, or the physiological changes which its administration effects. Abiding by such a standard, which has the advantage at least of being real and definite, and ceasing to connect both symptoms and remedial effects immediately with that conjectural and indefinite entity, a nosological disease, practitioners would in all diseases see their way more clearly, and proceed more directly and effectually to their object. Such mode of observing disease, too, would render the misconceptions and discrepancies of practical writers harmless, and enable the practitioner to unravel any complication of symptoms however intricate. As diseases are too much regarded in their complex and individualized character, so is it too much the habit to view the operation of remedies in connexion with the more remote curative effects, rather than with their more direct influence on physical functions. The former mode leaves out of view much that requires to be intimately known, and may well be characterized as empirical; the latter alone can lead to just and accurate conceptions of morbid actions and remedial agencies; and in proportion as it takes a lead in guiding the practitioner's treatment, is his practice entitled to be considered rational and scientific.

Some correct views on this subject have lately been presented by Dr. Spillan of Dublin, in a small volume entitled "A Supplement to the Pharmacopœia." Even where remedies evince what is deemed a specific operation in the cure of certain diseases, their effects can be very generally resolved into their primary and direct influence on certain functions of the frame, and their curative agency be thus satisfactorily accounted for. This, at least, should be attempted in all cases of alleged specifics, although, however minute and accurate the investigation, something will ever remain undisclosed in the properties of each drug, to give it its peculiar character, and distinguish it from others of the class to which it belongs. Rhubarb, jalap, aloes, colocynth, are all purgatives, and with a view to their purgative effect are they principally employed; yet practitioners discover grounds of choice which lead to selection and preference independently of their relative strength as purgatives. When they are administered, however, it is the purgative operation that is sought for, and through this operation the curative effect is expected. It should be so with all remedies so far as our knowledge of their direct agency admits. To this agency we should more particularly direct our attention, at the same time that we avail ourselves of every advantage which unexplained properties may afford in combating diseases. A specific for gout has always been considered a desideratum, and mankind have ever been deluded by the vain hope that one would be discovered. Absurd as is the search pursued with this view, it has conferred one advantage at least, by making us familiar with a medicine which, though not entitled to be called a specific, is yet highly valuable, not only in gout but in almost all inflammatory diseases. The medicine to which we allude is colchicum, and from a tolerably extensive employment of it for several years, we can faithfully add our testimony to the several records which attest its virtues and utility. When we were first induced to make trial of it, we took some pains to ascertain by close observation its real powers, and the best mode of administering it; and as our subsequent experience has made no change in the conclusions at which we then arrived, we cannot do better than transcribe here the account which we rendered of it in a small volume published in 1822. "A full dose of this medicine purges copiously, allays pain, and lowers the pulse. These effects are produced with greater certainty if the fulness of circulation be previously reduced by bloodletting, and the mucous secretions of the intestines evacuated. When inflammation is high, as marked by a strong bounding pulse, hot skin, and loaded tongue, bloodletting should always precede the use of colchicum. But in cases where arterial action is more moderate, and direct depletion from any cause questionable, this medicine may be resorted to with peculiar propriety and eminent advantage. Its operation seems to combine the several advantages of bleeding, purging, and sedatives,

and is therefore particularly adapted to those cases where active depletion is inexpedient. In treating hereafter of the several modifications of gout, in so many of which venesection must be sparingly employed, or wholly withheld, I shall have occasion to recommend the free employment of this valuable remedy. And as the forms in which this medicine is given, and the modes of administering it are of much importance, I shall fully explain my own practice in both respects, without presuming, however, to limit the application to those methods which I have been led to prefer. Various preparations and different modes of exhibition may, in the hands of other practitioners, be quite as salutary as those which I employ; for as I observed on a former occasion, the effect, not the form, of prescription deserves regard. The preparations which I have tried are the vinous tincture of the root, the vinous and spirituous tinctures of the seeds, and the powdered seeds. Of these I decidedly prefer the tinctures of the seeds, as being more uniform in strength, and more certain in operation. It might be reasonably expected, from the virtues of colchicum being found to reside in the seeds as well as in the root, that the former would yield a medicine of greater uniformity, being in a state of more perfect and determinate maturity, requiring less care in the collection and preservation, and being less liable to have their powers impaired. My experience of the several preparations fully confirms this supposition.

"It has been already remarked that colchicum purges, abates pain, and lowers the pulse. Its sedative powers, though sensibly connected with its evacuant, are not, however, wholly dependent on them. The motions produced are copious, frequent, and watery, and the operation seems more analogous to that of the saline purgatives than of any other cathartic. The number of motions is sometimes considerable, without any proportionate depression of strength ensuing. I have known even twenty stools occasioned by a dose of colchicum, the patient not complaining of the least debility.

"These circumstances will guide our employment of this medicine as a remedy for gout. Where the plethora is considerable, undoubtedly bloodletting should precede its use, for colchicum seems to remove the more fluid parts of the blood only; and these being quickly renewed, the relief obtained by this medicine alone cannot be so perfect or permanent as when bloodletting is also employed. Though the sedative powers of colchicum are valuable assistants to bloodletting in abating arterial action, they are yet no perfect substitute for this remedy in cases of high inflammation; neither are its evacuant qualities capable of superseding those cathartics which expel mucous secretions. In cases, then, of active gout occurring in a full habit, we would invariably bleed, and purge with calomel and antimony before having recourse to colchicum. It is possible that colchicum might occasionally diminish pain and abate inflammation more speedily if administered earlier; but it should never be forgotten that in the treatment of this and all other

diseases the important object is not to allay pain or combat symptoms, but to restore general health with the least possible injury to the functions or structure of particular parts. In this respect the physician's province seems analogous to that of the Roman dictators, who were appointed, not to combat an enemy nor quell an insurrection, but to take care that the commonwealth received no injury. In like manner the physician should provide not for the relief of a mere transient or other incidental ailment, but should so conduct the disease to its termination that no permanent injury be inflicted on the constitution. Unhappily, far from being left to the uncontrolled exercise of his judgment in accomplishing this end, he is too often compelled by prejudice and caprice to adapt his practical treatment, not to the real nature of the disease, but to the preconceived notions, impatience, and ignorance of those by whom he is surrounded. When colchicum is to be employed, it may be given either in full doses so as to purge actively, or in divided doses frequently repeated. A drachm, drachm and a half, or two drachms, of the tincture of the seeds should be administered at night, and repeated, if necessary, next morning. This quantity will generally purge briskly, but if it fail, a third dose the following night will be pretty sure to succeed; at least I have seldom found it necessary to exceed these doses. The full operation being thus obtained, I usually continue its use in smaller doses, ordering twenty minims three times a day in any of the common saline mixtures. Even this dose will occasionally purge so actively as in a short time to require its discontinuance, in which case the antimonial salines should be given without it, so long as febrile symptoms render necessary."

Such were the views which careful observation of the properties and medicinal effects of colchicum led me to form ten years ago, and it is somewhat in proof of their accuracy that a tolerably extensive use of the remedy in the intervening period has induced no change in them, while it has increased our confidence in the efficacy and utility of the remedy when used as an auxiliary to more active and direct treatment. What might be regarded as its specific powers seem resolvable into those more simple and direct influences which it exerts on the animal frame. It purges, allays pain, and lowers the pulse. These effects are accounted for by assigning to it a cathartic and sedative operation, and it is this combination perhaps to which its peculiar virtues are to be ascribed. The reduction of pulse might appear a result of its purgative operations, but it can without purging lower the pulse. That it possesses sedative properties is abundantly shewn by its effect in allaying pain, and this where no purging is occasioned; and, so far as we have been able to observe, we should consider the reduction of pulse as produced by its sedative rather than its evacuant properties. We are also disposed to regard the sedative properties as those from which it derives its chief value. These discus-

sions are important, as they assist in reconciling the discordant testimonies which are still offered on the subject, and when finally closed, will establish that discriminating use of the remedy which will ensure its fullest advantages.

It has been alleged, repeatedly and on highly respectable authority, that colchicum does no good unless it purges. This we disbelieve, because our own experience contradicts the fact, and because it is inconsistent with what we have witnessed of the other properties possessed by colchicum. On the principle of a purgative effect being required, several practitioners combine the remedy with purgatives, and with advantages well calculated to confirm the propriety of so doing. This mode we repeatedly tried in our early use of the medicine, but saw no inducement to pursue it. On the contrary, if we had a difficulty in exhibiting colchicum, it arose from its too great readiness to purge, and the consequent necessity of relinquishing it. When we need its availing powers in allaying the inflammation of gout, rheumatism, or any other disease, we are always best pleased when it does not speedily purge. In other words, we look for benefit more to its sedative than its evacuant operation; the latter can be supplied by other and better means; in the former it possesses advantages peculiarly its own. The explanation of these different opinions is not difficult: it must be sought in the views of those who administer the remedy, and the practice which they conjoin with it. If it be used as a specific, and without previous bloodletting, then we can readily understand that unless it purge it will be of little avail; but if the pulse be lowered by adequate bloodletting, and the bowels cleansed by calomel and colocynth, we would then say that a purgative effect from the colchicum itself is not needed nor at all essential to its beneficial operation. For the active gout of vigorous habits we would not give colchicum in full doses, or with a view to purge, but we would bleed and purge as in the ordinary treatment of the phlegmasiæ, and then conjoin colchicum in small doses with the ordinary febrifuge salines. Even when given in this way it will oftentimes purge actively, and, as we consider, to a disadvantage; for when it begins to excite the bowels, it must be at once relinquished, the continued irritation becoming intolerable, and, as we suspect, not very safe, although, having ever been cautious, we have never witnessed an instance of mischief thus occasioned. The views here presented we would wish to be scrutinized, for if correct, they would lead to a use of the remedy more precise and direct than yet obtains, and encourage practitioners to profit by its aid even when no sensible effect is immediately produced by it.

And here we cannot resist offering a remark which appears to merit attention. In former times, the *Materia Medica* was encumbered with a mass of frivolous and inert medicines, and thence rendered so unwieldy that some retrenchment became indispensable. The more worthless were cut off with no sparing hand, and it may be doubted whether some were not thus expunged from the list which might have

been beneficially retained. However this be, there sprung from this kind of investigation a scepticism respecting the virtues of all medicines which did not evince a direct and determinate influence on some function or other of the frame. The same feeling carried into practice demanded that each dose of a medicine should produce a sensible effect, and from this tendency it is that we think error has sprung. Although in active and urgent disease, requiring prompt relief, we would employ the full and adequate agency of remedies, yet in a large portion of medical practice, and especially where long established or habitual morbid actions are to be corrected, we are persuaded that more good results from their more gradual and oftentimes imperceptible operation. When morbid actions have continued for a certain time, and still more where structural changes have commenced, the organs and tissues concerned are not capable of sudden change, nor can they by any activity of treatment be brought back immediately to a healthy condition. As the morbid change is gradual, so also must be the corrective process, whether instituted by nature or promoted by art. In effecting it nature is ever slow and deliberate, and in this respect art would oftentimes do well to follow her example. When it is once ascertained that a medicine does possess active properties, it should not be suspected that these should be evinced by every dose of the remedy administered, nor should it be concluded that the remedy is inert merely from the absence of immediately sensible effect. This consideration would be to us a sufficient reason for placing a certain confidence in small doses of colchicum, even if we looked only to its specific or curative effects. When we regard the simpler properties into which these effects are resolvable, we are still more confirmed in the propriety of not withholding such doses on the mere ground of their not acting on the bowels.

Many remedies are continually administered from confidence in their accustomed properties, without an immediate or directly sensible effect being expected. Antimony is conjoined with salines to render them more febrifuge, and the effect is expected to result from its primary operation on the stomach; yet the evidence of nausea is not always insisted on, nor is it inferred, from the absence of nausea, that the antimony is useless. When the primary operation of colchicum comes to be better understood, it will be given in imperceptibly operating doses, with as much confidence as is now felt in the exhibition of antimony.

By the treatment prescribed in the foregoing pages the paroxysm of gout may be promptly and effectually relieved, the constitution re-established, the powers of the affected limb preserved, and the gouty disposition diminished. A due attention to prophylaxis may afterwards prevent its ever recurring. The value of such practice is most conspicuously displayed when contrasted with the negative treatment so generally resorted to, by which the paroxysm is greatly prolonged, the constitution very imperfectly relieved, the structure of the joints sooner or later utterly disorganized,

and the gouty diathesis confirmed and rendered inveterate. If gout were always of an active character, and confined to constitutions naturally vigorous, it is highly probable that the medical treatment would never have been perverted so egregiously as it has been. But this disorder occurs under every condition of health, and in all degrees of animal power, from the highest vigour to that helpless debility which can scarcely generate a paroxysm. Cases of this latter description will not bear active discipline; if employed, the patient must sink rapidly under it; and the danger arising from such maltreatment has no doubt been often the means of exciting an alarm well calculated to make a deep impression on those who are more peculiarly liable to this disease.

The too frequent error, too, of prescribing for the name of a disease rather than its peculiar condition, may have oftentimes caused extensive injury to result from ill-judged activity of practice, and thus have contributed to bring this method of treating gout into disrepute. Be the causes what they may that have so often occasioned active practice in gout to be resorted to by practitioners and again abandoned, it must be evident that, if this disease in its simplest form and highest intensity is so essentially benefited by the measures here prescribed, a modification of the same practice must, upon every principle of sound reasoning, be applicable to all inferior degrees of the same malady. From this conclusion not even the most timid need take alarm, for as the circumstances of each case sufficiently indicate what evacuations may be safely employed, no rational practitioner can ever be tempted by the doctrines here maintained to carry them beyond the point of safe and salutary endurance. Indeed there are many strong inducements to keep far within it; and provided the principles of treatment be not compromised from vain apprehension or too great pliancy of disposition, we should not be anxious in a great number of cases for the practice to be carried to the utmost limit of even safe and salutary employment; for as medical aid must necessarily be administered by men of various capacities and acquirements, all of whom may not be equally qualified for adapting accurately, in the details of practice, what principles enjoin, it will be the safer course to fall short somewhat of that activity which would most effectually relieve, rather than run any risk of exceeding it. These prudential considerations will have their full weight with every practitioner however enlightened. The more intelligent and experienced will of course feel more confidence in their own powers of accurate discrimination, and will pursue proper means with greater energy and less hesitation. All, however, must yield occasionally to prejudices long established, and to fears which the sensitiveness of friends cannot always relinquish or control. But the practitioner will give way to such impediments with greater safety to his patients and more satisfaction to his own feelings, by keeping steadily in view the principles here inculcated, and regulating his practice in

modified obedience to their clear and forcible dictates.

Before dismissing the consideration of the simple and active paroxysm, a few points more are to be noticed. It has been remarked that in the local inflammation two stages may be occasionally distinguished, one being primary, the product of the paroxysm, running a determinate course and spontaneously subsiding; the other secondary, dependent more on the general inflammatory diathesis than on the gouty nîsus, and tending not to spontaneous decline, but to disorganizations destructive of the mobility of the joints, and leading to eventual decrepitude.

Under the natural course of the paroxysm, and especially when the violence of this is subdued by suitable constitutional treatment, the first or purely gouty inflammation needs no local applications. The secondary requires direct and suitably active treatment for its removal. Leeches, cold or tepid lotions, and eventually blisters may all be necessary. On this head it may suffice to remark that the safety and efficacy of such local treatment must ever be proportionate to the relief antecedently given to the general constitution. If the constitutional derangement be corrected, the gouty nîsus will not recur; and the secondary inflammation may be subjected to ordinary and appropriate treatment without hazard of metastasis either to other joints or to vital organs.

So soon as decline of inflammation, whether primary or secondary, permits, early return to moderate exercise is of the first importance. It becomes then the best agent in restoring free circulation to the several weakened tissues, in obviating morbid depositions, and promoting the absorption of whatever may have taken place; thus preventing the thickening of ligaments, rigidity, and the contractions so apt to ensue, and enabling the party speedily to enter on the more active exercise which prophylaxis enjoins. And the precept is the more to be relied on, as it applies equally to other articular inflammations from whatever cause they arise, whether rheumatism, accident, or any other. Provided the cavity of the joint be not involved, (and in a large proportion of cases the inflammation is wholly exterior to it,) protracted rest is injurious, and the source of much mischief. Under it parts become rigid, of which early return to exercise would preserve the flexibility; depositions take place, producing permanent thickening of ligaments, or loading the bursæ of the tendons with glairy mucus, in either case impeding motion. The muscles too, consigned thus to inactivity, in time waste and become enfeebled; and eventually complete decrepitude with broken health ensues. From what has been said respecting the prophylaxis of gout, it must be evident how sedulously every source of impeded motion should be avoided by gouty patients whose joints have yet escaped disorganization. Such patients have themselves remarked that, when compelled by circumstances to use their limbs early after a paroxysm, they have recovered

with less impaired powers than when they have been enabled to indulge in rest. The principle is unquestionable, and no sensibility to slight pain, nor any vague apprehension of renewing the paroxysm, should be suffered to prevent the early renewal of moderate exercise, so necessary for promptly restoring the mobility of the joints, and preserving to the individual the power of still further re-establishing his health through their instrumentality. The attenuated limbs of gouty and rheumatic subjects are more owing to suspended exercise than to any effect of the special maladies. So convinced are we on this point, that we would in our own person infinitely prefer hazarding a renewed paroxysm either of gout or rheumatism, to encountering the manifold evils which protracted rest is sure to occasion.

Only one source of constitutional derangement has been hitherto noticed in this essay as connected with gout, namely, that which arises from excess of nutritive matter in the blood. Another no less important requires now to be discussed, as materially concerned in the several modifications of gout which are yet to be considered. It is the vitiation of blood which arises from the excrementitious matter continually carried back to it by the absorbents, not being adequately excreted and expelled. Health requires that the nutritive matter taken into the system should not exceed what is needed for the due nourishment of its several parts, and also that it should be duly appropriated to all the structures which compose the body; it also requires that the effete matter, which, having done its duty, is displaced by the nutritive particles deposited, and which in the ordinary course of animal functions is carried back into the blood, should through the admirable agency provided by nature, be from thence regularly and adequately discharged. If nutritive matter be taken in excess, it either increases the bulk of the body beyond the bounds of full activity and vigour, or, producing excitement tending to its own appropriation or removal, but also if too long continued generative of disease, it begets a state of fever or inflammation more or less active. On the contrary, if the excrementitious matter be not adequately expelled, it accumulates in the blood, vitiates its quality, and depraves the nutrient and other secretions, thus impairing by a slow and insidious process health and strength, and laying the foundation of a direful class of chronic maladies. Temperance in diet is the only safeguard against the former, but it is a certain one; exercise is also necessary for obviating nutritive plethora, by promoting the healthful appropriation of the nutriment taken, while it is the chief means of keeping in due activity the several excretory processes by which the effete matter of the system is eliminated and expelled. Of excrementitious redundancy only a brief account can be rendered in this place, the fuller discussion being more appropriately given in conjunction with PLETHORA, with which it is so continually intermixed.

As excess of diet gives rise to nutritive

plethora, and as deficiency of exercise both contributes to the same end by retarding the appropriation of the nutriment supplied, and promotes further vitiation of the blood by loading it with excrementitious particles, it is obvious that the two states of redundant nutritive matter and accumulated excrementitious particles may co-exist in every conceivable proportion. As each in its simplest state is characterised by its appropriate phenomena, the several combinations admit of being detected by enlightened and diligent scrutiny; and to this end would enquiry be far more profitably directed than to searching after specific agency in drugs for correcting evils which, having their origin in a primary depravation of the source of all nutrition, can never be radically cured but by means corrective and preventive of the primary mischief which occasions them. These pathological views point out the high importance of temperance and exercise as means both of preserving health and correcting disease. So far, at least, as the former purpose is concerned, all theories will concur in this recommendation, which is too firmly founded on common sense to be shaken by any speculation, while the advance of true pathology will maintain the equal importance of bearing the principle in mind in combating diseases.

From not being provided with a better term, we have on former occasions designated the accumulations of excrementitious matter in the blood as excrementitious plethora; and though we like not the name, we must continue to employ it. We do so with less reluctance from the necessity which exists for considering both nutritive and excrementitious plethora in conjunction, their various intermixtures being such that it would be impossible wholly to sever the discussion of them. Some future day, when the pathology of the blood shall receive the attention which is pre-eminently due to it, better terms than either can be readily substituted.

Gout being a disease no less of indolence than of repletion, it is manifest that its subjects are among those whose blood is vitiated by retained excrementitious matter as well as by redundancy of nutriment; and this consideration explains why mere abstinence, unassisted by active exercise, can never be expected to eradicate gout. Though the diet be temperate, yet indolence begetting general languor of frame, and this languor being confirmed and perpetuated by the effects of excessive excrementitious matter, causes a languid and imperfect appropriation of whatever sustenance is taken; a degree of nutritive plethora thus relatively ensues, and the elements of acute disease are thus supplied. To distinguish both states and their multiplied combinations, it becomes necessary to display their separate conditions, and by contrasting them with each other, to furnish indications by which the prevalence of either, or the intermixture of both, may at any time be detected.

The phenomena of nutritive plethora, its increase, and final transition into a febrile state,

have already been sufficiently described. Excrementitious redundancy in the blood begets a very different condition, but one no less marked by its appropriate indications. These are a sallow aspect and dusky skin, the pulse low, soft, and easily compressible, the surface of the body for the most part harsh, dry, and obviously deficient in natural transpiration, the tongue moist, clean, red; the appetite capricious, often craving, with an endless train of dyspeptic ailments; the alvine discharges inveterately foul, dark, slimy, pitch-like, and exhibiting no traces of healthy fæces; the urine high-coloured, often fetid, and depositing more or less of sediment: these several evidences, or a certain portion of them, with decline of flesh and strength, are sufficiently characteristic of this state. The condition itself we believe to arise from imperfect elimination of excrementitious matter; and the depraved state of the several excretions we regard as resulting from the laboured though inadequate efforts of the constitution to accomplish its own purification. How much this state is combined with the more advanced and complicated conditions of gout will be readily perceived; and it is by bearing in mind this source of vitiation, as well as that furnished by nutritive plethora, that the treatment will be most judiciously and successfully conducted. The direct effect of excrementitious plethora is unhealthiness of nutrient secretion, producing feebleness of the organs thus imperfectly nourished, and progressive decline of strength. The efforts of the constitution to throw off this oppressive load fail of success, and their ineffectual renewal, as well as the progressive unhealthiness of nutrient secretion, cause still greater feebleness, and eventually attenuate the frame.

According as more or less of nutritive plethora becomes combined with this state, the constitutional efforts are greater, and various degrees of febrile and inflammatory excitement ensue. In proportion as this excitement is energetic, and as suitable means are employed to relieve it, is the vitiated state of the blood corrected, secretions and excretions are improved, and general health and strength are renewed. Increased secretion from the bowels seems the principal discharge by which nature in general aims at getting rid of such impurities, and to promote them by suitable purgatives is clearly indicated, care being taken at the same time to support strength by light yet nutritive diet. When relief to a certain extent is thus afforded, the powers of the constitution rally, and a febrile effort is made to assist in the work of purification. As this advances, depletion requires to be more active, and the diet less stimulating. When sufficient excitement is aroused to warrant the employment of bloodletting, we may then consider the curative process in the most favourable train. Perhaps the powers of the constitution are hardly adequate to rectify any high degree of this peculiar derangement, without the agency which febrile excitement supplies; and hence we see experienced practitioners often hail the

appearance of febrile symptoms in chronic complaints, as announcing a more remediable form of disease.

These remarks on excrementitious plethora, though cursory and imperfect, will suffice to prepare the way for the remaining discussion of gout. To pursue this methodically through all the alleged varieties would be both tedious and valueless. If the principles be clearly laid down, there can be little difficulty in applying them to whatever variety or complication of the disease may present itself.

On a first accession of gout it should be the inflexible determination of the party assailed never to subject himself to a return. That this is practicable is abundantly proved; and if the means so clearly pointed out be not employed, blame should not be imputed either to the inveteracy of the malady or the imperfection of medical science. Nature has endued all matter with determinate properties, and living beings are subjected to certain organic laws, by obedience to which health and physical welfare are maintained, while a violation inevitably begets disease. They who will neither learn those laws, nor abide by them when proclaimed, must suffer the penalties of their own ignorance and perverseness.

When successive attacks of gout have taken place, the hope of effecting complete exemption must be sensibly weakened. Still, if there be no disorganization, the end may yet be attained, and at all events the attempt to accomplish it will be amply repaid; for should attacks recur they will be slight, at long intervals, easily subdued, and will commit no ravages, but leave the general health and even the gouty limbs tolerably sound.

Disorganizations of course enhance greatly all the difficulties. They evince a more confirmed gouty diathesis; the local weakness encourages renewed seizures from slight causes; and the impediment to active exercise cuts off one of the most efficient prophylactic agents. In this state of gout, then, too much should not be attempted, either by bloodletting or abstinence. Active symptoms should be met with such certainty of practice as the accompanying state of constitution may warrant. Fever should be allayed, local inflammation abated, and general health restored as speedily as possible; but all due regard should be given to the degree of constitutional power existing.

In the wretched cases of extreme disorganization, broken health, and exhausted power, no one would think of employing any but palliative treatment; but even this will be beneficial in proportion as it is guided by the principles maintained throughout this essay. So long as there is encouragement to employ bloodletting as part of the treatment, will benefit result from resorting to it. In cases in which the danger to be apprehended from its use is greater in degree than the expectation of benefit, other means must be substituted; and here colchicum is of inestimable value, sup-

plying the place of more active and efficient treatment better than any other drug with which we are acquainted.

As a healthy state of each function is the standard with which the several derangements should be compared, and which it should be the endeavour to restore, care should be taken to ascertain by direct evidences that each is actually restored to the efficient exercise of its powers. The pulse, skin, and tongue, will demonstrate with sufficient accuracy whether fever is subdued, and will thus afford evidence of the circulation being, for the time at least, restored to its healthy balance. To maintain this ground, however, assiduous care should be devoted to the several excretories, all of which should perform adequately their several functions. The skin, bowels, and kidneys should be active, and their respective efficiency should be attested both by the quantity and quality of their several excretions. Each of these should receive more continued attention than is usually given to them, for if duly noticed, they would announce the advance of disease long ere depraved sensation or other prominent derangement indicate its approach, and would thus lead to a more timely and effective use of suitable correctives.

A closer attention to them, also, during convalescence, would contribute much to render recovery more perfect, and lessen the liability to renewed attack.

The skin should be active, for it is an outlet for the discharge of excrementitious matter of the highest importance. The most effectual and salutary means of keeping it so is active exercise. Warm bathing is a valuable assistant, and eminently so when but little exercise can be taken. The condition of the skin itself should be regarded. In many, large portions of its surface are hard, dry, scaly, and utterly impermeable. These should be restored by warm bathing, by such applications as soften the cuticle, and by frictions both with the hand and the flesh brush. The thorough desquamation of cuticle effected by the process of the Russian vapour-bath, would be a valuable means of restoring many an imper-spirable skin to the full exercise of its functions. A freely perspirable skin is powerful in obviating plethora both nutritive and excrementitious.

The bowels should perform effectually the duty which nature assigns them, and in this respect attention is much needed, for considerable depravation is continually suffered to go on unchecked and unheeded. The amount and frequency of stools are too much trusted to as evidences of healthy bowels, while the only one to be relied on is the character of the matter discharged. When this, however sufficient in quantity or regular in discharge, is dark, foul, and charged with mucus, evacuant or alterative medicine is needed, however free the party may be from every other symptom of disease. By this neglect much disease creeps in, and many a constitution is undermined where timely and judicious

attention to the bowels would avert all the mischief.

In like manner the urine merits attention, and more especially from the tendency which there is in gout to throw off morbid matter by this outlet. Much profitless scrutiny has been devoted to the different impregnations, the specific gravity, and other properties of gouty urine. The main fact respecting it is that it contains what ought not to find its way into it, and the most effectual way of purifying it is to cut off the morbid supplies by regulating the diet and restoring due activity to the other excretories, for it is their deficiency which throws upon the kidneys so much extraordinary labour. Light diet, a free skin, and active bowels will clear the urine with little aid from chemical correctives. These are, no doubt, proper as adjuvants, where high degrees of acescency or of alkaliescence prevail; but they are utterly inadequate for perfect corrections, and their use at best, if alone trusted to, is uncertain and short-lived. We have no evidence that when taken by the mouth they ever reach the bladder so as to act on the concretions deposited there. This truth the history of calculous complaints establishes. From the same source we learn that when acid calculi cease to be deposited in consequence of the free use of alkalies, if these be continued, alkaline depositions take place, and thus the evil is changed, not removed. Both in calculus and gout our belief is that more may be done in correcting the morbid state of urine, by re-establishing a healthy balance in the constituents of the blood, avoiding all excess of diet or stimulants, and keeping up an active state both of cuticular and intestinal excretion, than can ever be effected by neutralizing remedies. These should not be withheld, but from the circumstance before mentioned caution is required in their use, and at all events they should not, however efficient they may casually appear, be suffered to supersede the far more effectual relief which rectifying the fundamental errors of the constitution is capable of affording.

Little more is needed to complete the discussion of gout, the principles maintained in the foregoing pages being applicable to all the forms in which the disease can present itself. It has been already stated that these complex conditions and alleged varieties are referable, not intrinsically to gout, but to the state of constitution in which it occurs; and to the constitutional derangements should the treatment be directed, without bias from the imputed cause. The varieties, when scrutinized, will be found to consist of gouty tendencies combined with visceral affections and with more or less of debility; and in treating them the object should be to restore general health, and thus reduce whatever gout there may be to its simple and intelligible state, rather than aim at improving health by any specifics supposed to act directly on gout. The latter mode has been tried sufficiently long and by sufficient variety of means to prove its utter inefficiency, and deprive it of all confidence. The history of specifics and their effects would

furnish a lamentable display of error and its consequences. The Portland powder appeared to cure, but the result of Dr. Cullen's inquiries was that not one of those who were so cured survived three years. Some died suddenly, while others were attacked with apoplexy, palsy, asthma, hydrothorax, general dropsy, or general cachexia. In this conclusion both Dr. John Gregory and Dr. James Gregory were led by their investigations to concur. The ravages occasioned by the *eau medicinale* are of too recent date to need more than a casual mention.

According as the general health is broken, and the power of bearing active treatment weak, must gouty patients abate in their expectations of cure, and be content to mitigate their sufferings by such means as sound principles sanction; and by adhering to these much may be done even in extreme cases. In all may fever be allayed, plethora prevented, the bowels kept free, the skin perspirable, and contingent derangements receive their appropriate correction.

In proportion as the natural vigour is slight, or reduced by excrementitious plethora, must depletory treatment be cautiously applied to recurring paroxysms; for no promptitude of relief could justify the hazard incurred by even an approach to excessive evacuation. While we contend for the inflammatory nature of gout, and the decided propriety of combating the active disease with proportionally active treatment, we are far from inculcating a rash or indiscriminate use of the lancet, but on the contrary would employ it with great caution, and only under those circumstances in which repeated experience had established both its safety and utility. With a full hard pulse, hot skin, and furred tongue, we would bleed, purge, and give colchicum without hesitation. Even where inflammation was less strongly marked we would employ the same means, provided the evidences of plethora and of febrile excitement were sufficiently discernible; and this treatment has in our own practice had perfect success in abridging the paroxysm, accelerating convalescence, restoring speedily the affected limbs, and greatly prolonging the period of exemption, even in cases of long continuance, where the duration, succession, and severity of paroxysms had induced such helplessness and decrepitude as confined the parties to the couch for two-thirds of the year. The vigour of constitution being the standard by which depletion should be regulated, it follows that when such vigour is deficient, measures of the same activity should not be pursued as are necessary when the habit is robust. In extreme cases, where natural languor and feebleness are confirmed and increased by the effects of excrementitious plethora, when muscular debility is great, the pulse low, soft, faltering, the tongue moist, clean, of a bright red colour, or scarcely whitened, the bowels inveterately foul, the gouty effort feeble and imperfect,—in such cases wine, stimulants, and invigorating regimen must supersede every evacuation save purging. The object in such

cases should be to renovate the frame by improving the bowels and giving tone to the whole system. Should the gouty effort, in consequence of such regimen, become more vigorous, and marked by clear evidences of renovated powers, then may an approach be made to the more effective treatment by which active gout is so signally relieved.

With respect to the nosological varieties, they may be dismissed with very few observations. Cullen has recognized them; namely, the atonic, retrocedent, and misplaced. The atonic is marked by general debility, feeble attempts to generate a paroxysm, and visceral derangements, chiefly gastric. Light food, regulation of bowels, and the several means suited for improving the stomach and giving tone to the general system, should be the means here resorted to. Light tonic medicines may be combined, but they are of little avail, and they should neither be given largely nor too long continued. The condition of the stomach is here analogous to what obtains in gastrodynia, to which head we may refer for the treatment which this derangement requires. What is generally called gout in the stomach is but a high degree of this affection; and when the spasm is intense, with prostration of strength, the strongest stimulants, such as brandy, ether, and laudanum, may be necessary to allay it. Immediately after, however, the stomach should be effectually cleansed of its mucous accumulations by full doses of calomel, antimony, and colocynth; and light cordials with aperients should follow, rather than direct stimulants or tonics. When there is great debility of stomach, chalybeates may be required, and they are best administered in the form of some natural or artificial mineral water. It is in such cases that the internal use of the Bath waters is so eminently serviceable, although they are valuable in most gouty cases, especially where the stomach requires some substitute for the wine and stimulants relinquished. In such cases the grateful stimulus of the Bath waters gives tone to the stomach, improves appetite, and renovates strength, thus accomplishing an unequivocal good; not, as has been falsely imagined, by the mere establishment of gout in the extremities, but by the reduction of gout to its simpler and more manageable state through the amendment effected in the general health. This advantage is great, provided it be rightly understood. If the mere gouty accession be the object desired, and that on its appearance the end is considered as attained, then indeed the benefit is but slight and transitory, while the false experience thence derived serves but to confirm error and perpetuate evil. But if the accession, when thus elicited by means of renovated powers, be regarded as it ought, and properly treated, the opportunity thus afforded for resorting to efficient measures is most valuable, and the Bath waters, so instrumental in procuring it, should receive the credit to which they are so justly entitled. It is curious to observe the fluctuations which take place in public opinion respecting the value of mineral springs. They become fashionable and again decline, not

from any variability in their properties or medicinal effects, but from the misconceptions and caprices to which ignorance is prone. It is lamentable to think how great is the ignorance of the public in all that relates to the structure and functions of their own frames, and how very inconsiderable a portion the science of animal life forms even of that course of instruction which our highest seminaries supply. Formerly Bath was the general resort of gouty patients in all stages and degrees of the disease. The object was not to cure gout, but to excite and hasten it; and as this effect was often produced, their reputation became established. In time it was discovered that in full habits and inflammatory states of constitution their agency was not always limited to bringing on gout, but that other excitements less harmless were apt to ensue. The local practitioners were therefore constantly obliged, in the conscientious discharge of their duties, to withhold the internal use of the waters, however they might allow their external application; and patients who were sent to Bath expressly to drink the waters were naturally disappointed. It came to be doubted, also, whether bringing on the paroxysm was to be considered an unmixed good; and this approximation to just views gave rise to further hesitation respecting the expediency of using the Bath waters. The consequence is that though vast numbers still resort to Bath for gouty complaints, the waters are not held in that high estimation in which they were wont to be regarded. Yet they still retain all the virtues which they ever possessed; are still capable of rendering most valuable services to gouty constitutions, nay, of effecting, in the improvement of stomach and renovation of strength, what no course of medicine, nor any other mineral spring in these countries, could equally accomplish; and there is no reason, save the capricious fluctuations of opinions, why they should not still maintain the high character which they formerly possessed. The objects in administering them may be different, but the effect of this must be to render them only the more serviceable.

Gout has been called retrocedent when the sudden subsidence of the gouty inflammation has been followed by sudden affection of some internal organ or function. Such affection is no doubt liable to occur whenever the local inflammation is repelled without the constitution being adequately relieved. Where it happens, it requires to be treated precisely as if gout were not concerned. If the substituted malady be marked by spasm and sinking powers, cordials and stimulants must be used; if by inflammation, then must bleeding and purging be employed to the full extent which the urgency of symptoms may demand.

The term misplaced gout seems to have been employed without any sufficient reason. It has been applied to any and every incidental disease occurring in a gouty habit. For the most part such disease has been inflammatory; and when it has attacked the stomach, lungs, or brain, practitioners, impelled by the urgent

danger, have not hesitated to bleed freely, however repugnant to such practice their ordinary views of gout might be. It would be difficult to reconcile this practice with the extreme timidity which shrinks from the employment of bloodletting when the inflammation of active gout is situated in the extremities.

HEADACH.—Cephalalgia, from κεφαλή, the head, and ἄλγος, pain. From a very early period the term cephalalgia has been employed to designate various kinds and degrees of pain affecting the head. Some authors, indeed, have confined its use to headachs of the more obtuse and transient character; including pains of a more severe, tensive, and continued kind under the term *cephalaea*. But the words are too nearly alike ever to preserve a separate and distinctive meaning. For all practical purposes it will be more eligible to adopt exclusively the term cephalalgia, as answering to our English word headach, arranging under it the more marked distinctions of headach as species and varieties.

From the intimate connexion which subsists between the sensorium and every other part of the system, it is not surprising that the head should participate in the morbid affections of those parts. Disorders of the stomach, liver, intestines, and uterus, especially, have long been observed to produce pains of the head. Nosologists have accordingly specified many kinds of *sympathetic* cephalalgia; but they have not been equally successful in pointing out the kinds of pain which arise from the diseases of the head itself. In truth, the difficulty of such an undertaking seems to have deterred them from making the attempt. They have too readily acquiesced in the opinion that, with the exception of some organic lesions of the brain, pain of the head almost always arose from morbid affections of other organs. Even the philosophic Cullen has given cephalalgia no place in his nosological system. Yet it would be truly astonishing if the head, itself so susceptible of impression from disorders of other parts of the system, should not suffer pain from some of its own. Many serious structural changes may indeed take place within the head unaccompanied by pain; but it is impossible to deny that numerous other morbid conditions of the brain and its meninges, as well as of the cranium and its coverings, do produce headachs of various and distinctive characters, and requiring a corresponding variety in the treatment.

One of the difficulties connected with the investigation of headach arises from the gradual and almost imperceptible conversion of pain, originally sympathetic, into an independent affection, which may remain long after the primary disease has been removed. Thus dyspeptic headachs not unfrequently induce

permanent disorder in the head, remaining perhaps for months or years as the habitual malady, although the original symptoms of indigestion may have been entirely lost.

Another source of obscurity may be traced to the frequent co-existence of disease in the head and in some other organ with which the head peculiarly sympathizes; each disease serving to influence and aggravate the other. Under such circumstances it is sometimes difficult to determine which was the original malady.

Allied to this difficulty is a third, arising from the simultaneous operation of several of the more powerful exciting causes of headach; such, for example, as immoderate mental excitement and stimulating potations, both upon the head and upon the stomach. Thus, intense application of mind may not only excite headach by its direct action upon the brain, but may at the same time produce evident disorder of the digestive organs. Without careful discrimination, such a headach would probably be ascribed solely to dyspepsia, to the neglect of the actual state of the brain; whereas the derangement of both head and stomach may be alike dependent on the undue excitement of the sensorium.

In no disease, perhaps, does the subject of *predisposition* require to be more attentively considered than in cephalalgia. Of the circumstances which especially predispose to headach we may enumerate the following:—

1. Original malformation of the head.
2. A highly susceptible state of the nervous system.
3. Debility, however induced.
4. General or local plethora.
5. The previous occurrence of congestive or inflammatory disease.
6. Habitual or frequent excess in wine, spirits, and other powerful stimulants.
7. Injuries of the head from blows, falls, &c.
8. Continued mental excitement.

The occasional or *exciting causes* of headach are very numerous. Some of them would produce the disease in almost any individual, even under ordinary circumstances; but the greater number only excite pain of head in persons already predisposed to the malady. Hence the great importance of estimating the degree of predisposition. Of the more frequent occasional causes we may specify:—

1. Rheumatic affection of the pericranium.
2. Inflammation, or a more chronic morbid condition, of the pericranium.
3. Inflammation of the mucous lining of the frontal sinuses, or foreign bodies within the sinuses.
4. Intense mental excitement.
5. Strong impressions on the external senses.
6. Excessive impetus of blood to the head.
7. Impeded return of blood from the head.
8. Congestion within the head.
9. Suppression of accustomed evacuations.
10. Inflammation of the brain or its membranes.
11. Tumours, or other morbid changes of structure within the head.
12. Morbid affections of the stomach:—as from over-excitation or distension; from irritating ingesta; from imperfect digestion; the presence of bile in the stomach, &c.
13. Costiveness.
14. Narcotics.
15. Worms.
16. Diminished pres-

sure of the atmosphere. 17. A heated, humid, or deteriorated atmosphere. 18. Sudden changes of temperature. 19. Exposure to a current of air, or to a cold wind, especially from the east.

This enumeration will sufficiently shew the impossibility of treating separately every variety of headach in a work like the present. Some leading distinctions of cephalalgia can alone be attempted; and such, we apprehend, may be satisfactorily comprised in the following species:—

1. Cephalalgia muscularis.
2. ————— periosteosa.
3. ————— congestiva.
4. ————— organica.
5. ————— dyspeptica.
6. ————— periodica.

Of these we shall now proceed to treat separately.

I. *Cephalalgia muscularis*.—This kind of pain is essentially of a rheumatic character, and particularly affects the occipito-frontalis and temporal muscles. The pain is tensive and remitting, sometimes diffused over the greater part of the head; at other times, varying its situation from the forehead to the vertex or the occiput, or from one side of the head to the other. In some cases, also, the pain extends to the face and teeth. Not unfrequently, the muscles of the neck and shoulders are at the same time affected with fugitive pains. The action of the affected muscles remarkably increases the pain and tension, as does also even slight pressure upon the scalp. The attack may be usually traced to some partial exposure to cold or humidity, as by sitting near an open window, or standing in a current of air after being heated by exercise. It is often preceded by a sense of coldness over the head and along the sides of the face. Some disturbance of stomach usually attends it for the first day or two, accompanied sometimes with slight febrile excitement of the system. These symptoms generally soon subside, even without medical treatment; leaving, however, an increased susceptibility in the parts to a renewal of the complaint from very slight causes. A dose of calomel and antimony, aided by a pediluvium, at night, and followed by a brisk aperient dose in the morning, considerably expedites the departure of the pain. In some cases of peculiar severity, diaphoretic remedies are required; and if the pain be very acute, leeches to the temples will afford considerable mitigation. But the principal aim of the practitioner should be to prevent a recurrence of the attack, by directing the patient to be much in the open air; to use a shower-bath daily, or, in its stead, the free affusion of cold water over the head; and every other practicable method of restoring the tone of the affected parts, and thus enabling them to resist the influence of cold and humidity.

II. *Cephalalgia periosteosa*.—This is an unusual form of headach, and has not, we believe, been hitherto described by authors. The writer of this article first pointed out its nature in a paper read before the Westminster Medical

Society in the year 1825. In many particulars, the periosteal headach resembles the muscular. As in that species of cephalalgia, the pain is diffused, tensive, and remitting, increased by pressure and by the action of the occipito-frontalis and temporal muscles. It may also be generally traced to the same exciting causes, humidity and sudden changes of temperature. The very parts affected in the merely muscular headach are equally involved in this; but, in addition, the periosteum is also affected, and the sensorium suffers more excitement. The pain itself is more deeply-seated and intense, and is attended with an augmented action of the external arteries of the head, as well as with more gastric and general febrile disturbance. The attack, moreover, does not so speedily subside; for although after a few days the muscular covering of the head can be moved without pain, and slight pressure no longer produces uneasiness, yet the periosteal pain and tenderness remain. Firm and deep pressure is still painful, and excites a sensation of distressing tension over the greater part of the head and face. The same kind of constrictive pain is produced almost invariably by going out of a warm into a cold room, or by taking off the usual covering of the head. The whole periosteum, indeed, of both the head proper and the face is implicated in the disease, although those parts of the membrane suffer most which are but slightly covered. Hence, the upper portion of the nose and the alveolar processes are particularly affected. We may here remark, as a striking proof of the periosteum itself being the immediate seat of the malady, that the pain is frequently transferred for a time from the head to the face, soon, however, returning to its more accustomed seat around the head. It is not less remarkable that an increased feeling of tension may be induced over the whole or the greater part of the head and face by firm pressure upon any one point of the periosteum, whether of the head or of the face. Hence we may conclude that the structure affected is one common to both head and face.

It may, perhaps, be supposed that the periosteal cephalalgia now described is only an aggravated form of rheumatic headach. It is, however, a far more complicated and intractable malady, and occurs, we believe, only to those who have previously suffered from continued cerebral excitement. In truth, a two-fold predisposition appears to be essential to its production:—first, a highly susceptible, if not also preternaturally vascular, condition of the brain or its membranes, such as is often induced by long-continued study or high mental excitement, as well as by the frequent occurrence of sympathetic headach arising from gastric or hepatic disorder: and secondly, a state of debility and exhaustion supervening upon that excited condition of head, whether occurring spontaneously, or as the result of the depletory measures employed for the removal of the previous cerebral excitement. If an individual, under these concurring circumstances, be exposed to a powerful exciting

cause, such as a sudden diminution of temperature, especially if accompanied by humidity, he may have the periosteal cephalalgia induced, —a disease of a singularly obstinate character, and apparently maintained by that condition of the brain or its membranes, which existed prior to the supervision of the external malady. On the other hand, the pain and irritation connected with the external malady tends, in its turn, to perpetuate the morbidly excitable state of the brain. The following case may serve as an illustration.

A gentleman of a susceptible constitution, who had long been subject to occasional attacks of dyspeptic headach, and had frequently suffered from mental application during a long and laborious course of study, was thrown at once into the onerous duties of a large public institution. Much pain and excitement of head ensued. General and local bleeding, mercurial purgatives, antimony, low diet, &c. were considered necessary. The symptoms subsided considerably, but the brain and nervous system remained in a state of extreme susceptibility. On some recurrence of pain, it was judged needful to shave the head, which happened to be done under circumstances of great exhaustion on a cold wet evening. The ordinary covering of a thin night-cap was alone worn during the night. On awaking from sleep, a severe constrictive pain was felt over the whole head, attended with heat and tenderness of the scalp, throbbing of the temporal arteries, considerable cerebral excitement, and vomiting. In truth, an external periosteal disease was thus engrafted upon a head previously suffering from high and continued excitement. After a few days, the more superficial tenderness subsided, but the periosteal affection proved exceedingly intractable. In this case it seems probable that the frequent occurrence of sympathetic headach, aided by the excitement attendant on long-continued study, had induced an undue degree of vascularity and of nervous susceptibility in the head generally; while the remarkable prostration of vital power consequent upon the depletory measures employed, served to increase the nervous susceptibility, and thus concurred to form that two-fold predisposition of which we have before spoken, and without which, we apprehend, the subsequent exposure to cold and humidity would have been insufficient to excite this peculiar periosteal cephalalgia, although it might have produced an ordinary rheumatic affection of the scalp. So exquisitely sensitive does the pericranium remain in these cases, so readily affected by every exposure to humidity or sudden reduction of temperature, and so apt to participate in every occasional excitement of the brain, that one attack of the complaint has scarcely time to subside before some fresh exposure gives rise to a decided augmentation of disease.

In the treatment of periosteal headach the first object must be to lessen the general cerebral excitement, as well as the inflammatory tendency and morbid sensitiveness of the affected membrane. Local bleeding, mercurial

purgatives, antimonials, the acetate or citrate of ammonia, and similar means, are best adapted to fulfil these indications. Opiates are of doubtful efficacy. Should much nausea occur at the commencement of the attack, an emetic would be advisable; after which a dose of calomel and antimony, followed by a saline purgative, will generally be found very advantageous. The utmost quietude of mind should be preserved.

After the acute symptoms have been subdued, vigilant attention will be necessary to guard against a relapse. The susceptibility of the pericranium may be moderated by the gradual use of cold washing, followed by gentle friction of the head, as well as by a free though prudent exposure to the open air in the way of carriage, horse, and walking exercise. A residence in a dry and somewhat elevated situation will materially conduce to the patient's recovery. But it must also be remembered that the morbid condition of the membrane may be maintained by undue cerebral excitement, and that therefore the discipline of the mind, the avoidance of intense or long-continued study, and every engagement and pursuit which may tend to perpetuate that excitement, are absolutely essential to a permanent cure.

Under the division of periosteal headach it may be proper to describe that affection of the pericranium which has been called by Mr. Crampton *periostitis*.* Cases in some respects similar had been previously published by Sir Everard Home,† and some important illustrations of the same subject have been recently added by that accurate and distinguished pathologist, Dr. Abercrombie.‡ Fixed pain of head and tenderness of some portion of the scalp, with a degree of thickening and swelling of the integuments, were the characteristic symptoms. The periosteum was generally found thickened, and, in some cases, the bone itself diseased. In the majority of instances, some affection of the brain co-existed with the periosteal disease. It would seem probable, however, that the periosteum was primarily affected in several of the cases adduced; in those, particularly, in which complete and permanent relief followed the division of the pericranium and the keeping open of the wound for a considerable time. Yet it must be allowed that even pains of head, apparently connected with internal as well as external disease, have been essentially relieved by such an operation. Mr. Brodie and the late Mr. Pearson have repeatedly cut down to the bone in cases of fixed and obstinate pain confined to a limited part of the head, maintaining afterwards a free discharge from the part, and with very decided success.

We might here without impropriety have introduced another kind of headach—that depending on a diseased state of the bones of the cranium, and attended with constant pain and tenderness at some particular spot; but as such cases

* Dublin Hospital Reports, vol. i.

† Trans. of the Soc. for the Improvement of Med. and Chir. Knowledge, vol. iii.

‡ On Diseases of the Brain and Spinal Chord.

are comparatively rare; we are unwilling to present it as a distinct species.

III. *Cephalalgia congestiva*.—This species is characterized by an obtuse pain affecting the whole or a part of the head, particularly the forehead and occiput, and is frequently attended with a feeling of general oppression and torpor. It may be observed in three different states of constitution:—in the plethoric; in the delicate and irritable; and in the weak and leucophlegmatic.

1. The congestive headach frequently attacks persons of a *plethoric* habit, who have passed the middle period of life, have lived freely, and have used but little bodily exercise. In such the countenance is often bloated, the eyes are full and red, the veins of the face distended, and the general expression dull and inanimate. It is more especially observed in those who have suffered from gout or from chronic diseases of the liver, and after the cessation of the catamenia. In such it must always be regarded with vigilant attention, as indicative of an apoplectic or paralytic tendency.

2. The congestive cephalalgia also affects the *delicate and irritable*, especially those whose minds have been injudiciously cultivated at the expense of their bodily health and vigour. Hence it is most frequently observed in the female sex. In persons of this temperament the sanguineous circulation is so nicely balanced as to be disturbed on very slight occasions. A vivid emotion of mind, earnest or continued conversation, an unusual degree of bodily exercise, or some irregularity in diet or in the action of the bowels, will occasion in such habits an increased impetus of blood to the head, which, though only producing at the time a sense of heat and excitement, is generally followed by coldness of the legs and feet, and by the dull oppressive headach of which we are now treating. In some cases, the pain is attended with flashes of light or with little floating specks before the eyes, as well as by noises in the ears. This species of headach is particularly observable in delicate females of an irritable temperament, both before and for a day or two after each menstrual period.

3. The congestive headach also attacks the *weak and leucophlegmatic*. It may be recognized in persons who have been reduced by acute diseases, by hemorrhages, leucorrhœa, &c. It is also seen in chlorosis and in various other asthenic conditions of the system. There is usually a slow and languid pulse, a pale, sallow, or even semi-transparent appearance of the skin, and a peculiarly heavy expression of countenance. The lips are generally pale, or of a slightly blue tint; the feet are apt to swell in hot weather or after exercise; and every muscular exertion becomes laborious and formidable. In this variety of congestive headach, the pain is most commonly in the forehead, although in some cases the occiput is chiefly affected.

The *treatment* of congestive cephalalgia must necessarily be adapted to the circumstances of each individual case. We may remark that,

in the first variety, that which is incident to the plethoric habit, venesection or cupping, brisk purgatives, a moderate diet, the affusion of cold water upon the head, and stimulating pediluvia, are usually required. When the attack has been subdued, the patient should be directed to avoid much mental application; to observe regular habits of exercise in the open air, as well as great moderation in diet, and a careful attention to the state of the bowels. The shower-bath should also be daily employed.

In the congestive headach of the weak and irritable, it may be sometimes necessary to have recourse to topical bleeding; but, generally, quietude of mind, a stomachic aperient, the application of cold to the head, either by the affusion of water or by evaporating lotions, stimulating pediluvia, and the exhibition of camphor and ammonia or other diffusible stimulants, will prove adequate to the removal of the attack. Every precaution should be used to prevent a recurrence of the complaint by increasing the tone of the system, and thus counteracting the undue susceptibility of impression and the irregular distribution of blood, with which the malady is peculiarly connected.

The third variety of congestive headach, that occurring in the weak and leucophlegmatic, requires nearly the same management as the last. In this, however, the loss of blood can scarcely ever be necessary, although blisters are sometimes indicated. Warm and cordial aperients, the moderate use of wine, camphor, valerian, or ammonia, aided by a mustard or other stimulating bath for the feet, are well adapted to remove the immediate pain; while good air, gentle exercise, a nutritive diet, cheerful society, with the assistance of tonic remedies, more particularly the lighter preparations of steel, are not less calculated to invigorate the constitution, and thus preserve it from future attacks of the complaint.

We now proceed to a very important division of our subject, viz. headach arising from organic disease within the cranium: this we have ventured to name, although the term is not unexceptionable,

IV. *Cephalalgia organica*.—So numerous and complicated are those morbid changes of the brain and its membranes which have been found to produce headach, that we must content ourselves with a reference to the most frequent of them; endeavouring chiefly to point out the principal symptoms which distinguish the organic headach from cephalalgia arising from other causes. Among the structural changes productive of headach, tumours are undoubtedly the most frequent. These may be either imbedded in the substance of the brain, or attached to its surface, or to the membranes surrounding it. Such tumours may be of a pulpy, adipose, albuminous, cartilaginous, scirrhous, or even bony consistence. Hydatids are another cause of headach, as are also spiculæ of bone attached to the dura mater, or growing from the inner table of the skull. In a case which occurred to the writer a few weeks ago, one of the clinoid processes

of the sphenoid bone was found unusually long and formed into a thorny point, so sharp and strong as to pierce the finger when pressed against it. A similar, though not equally long point, was found to have grown from the squamous portion of the temporal bone. In some instances the membranes of the brain have been found thickened and partially disorganized; in others a portion of the brain has exhibited a softening or degeneration of its structure, or one or more abscesses imbedded within its substance.

In many of these diseased conditions, the pain of head may remain, during a considerable period, unattended by any other prominent symptoms: at length, however, some decisive indication of inflammatory action or of cerebral pressure occurs; the sight or hearing, for example, becomes affected, or the powers of the mind become enfeebled, or simple convulsion, epilepsy, or paralysis announces the extension of disease.

The diagnosis of cephalalgia organica is often difficult at an early period, while the pain is unattended by any morbid affection of the senses or of the moving powers. In general, however, we may remark that the pain itself is more fixed, deep-seated, and habitual than in other kinds of headach; more independent of the state of the stomach; more obviously increased by mental application, by close or heated rooms, by stooping, and sometimes even by the horizontal posture. The same degree of cheerful conversation which would chase away, or at least suspend the feeling of, ordinary headach, often becomes laborious and almost insupportable in organic cephalalgia. Nor is the effect of stimulants received into the stomach less remarkable. Wine and other fermented liquors produce an immediate aggravation of pain. When the disease has considerably advanced, even a slight motion of the head will sometimes give rise to extreme suffering, and also to vomiting. It is proper to add that the disturbance of stomach which is sometimes present in this species of headach may occur without any apparent disorder of the stomach itself, and in this respect, as well as in others, differs materially from the sickness incident to dyspeptic headach. Moreover, the pain in organic cephalalgia equally remains when the sickness ceases. We have said that the pain in organic headach is fixed and habitual. There are, however, exceptions to this general rule. Sometimes the pain is of an intermitting character, although serious structural mischief may be steadily advancing. In such cases, the most vigilant attention to the collateral symptoms will be required before the real nature of the case can with any reasonable probability be determined.

V. Cephalalgia dyspeptica.—This may be regarded as the most frequent kind of headach. In many individuals it is induced by very slight errors in diet, or even by remaining somewhat longer than usual without food. It may occur without any remarkable or at least very obvious degree of susceptibility in the

brain. We see it, for example, in persons who can bear close application to study without any apparent inconvenience to the head itself, while yet very liable to headach from taking certain articles of food, or mingling them in too great a variety. Yet, in the majority of instances, it must be allowed that dyspeptic headach is most frequently found in those persons who also suffer from much mental excitement, and in whom the gastric disturbance is only one effect of that excitement. In such, the stomach may become either morbidly irritable or in the opposite state of atony, being, in either case, equally unfit for the due performance of the digestive functions, and therefore liable to be still further deranged by any irregularities in diet. The dyspeptic or stomach headach, when severe, more particularly affects the left temple, extending sometimes over the same side of the forehead, and producing tenderness in the corresponding ball of the eye. In other instances, the whole forehead, or even the greater part of the head, becomes painful. The pain may be either dull and oppressive, or of a more acute character, and in both cases renders mental exertion difficult and irksome. It is not unfrequently attended with some tenderness of the scalp, and an increased pulsation of the temporal arteries. The paroxysm of dyspeptic cephalalgia usually commences when the patient first awakes in the morning from a heavy sleep. The pain, at first diffused and oppressive, gradually concentrates itself upon one or other temple, generally the left, and becomes more and more acute. A degree of nausea often supervenes, sometimes increasing to sickness and vomiting. If the latter occur, the remains of an undigested meal, or merely an insipid fluid mixed with frothy mucus, is perhaps first ejected; but if the action of vomiting continue long, some admixture of bile usually follows. In some instances the stomach throws off, on the first attempt, green or yellow bile, or a fluid extremely acid and irritating; in which case, the pain of head is sometimes immediately relieved.

If neither vomiting nor aperient medicine be employed to check the ordinary progress of the paroxysm, the pain generally becomes more severe as the day advances, until it is lost in sleep. Occasionally, it remains during the greater part of the second day. When, however, an active dose of purgative medicine has been taken, the headach often becomes less in two or three hours, and ceases altogether in six or eight. It is remarkable that the beneficial effect of a stomachic and antacid purgative is frequently felt long before the offending matters are expelled from the bowels, clearly indicating that the sources of irritation were either in the stomach itself, or in the upper portion of the intestines.

Such is the usual course of a sick headach when occurring as a distinct paroxysm. The dyspeptic cephalalgia may, however, exist in a more chronic and habitual form, and in every possible degree. It may also be very transient in its duration. Many individuals suffer more

or less inconvenience after every principal meal, unless they limit themselves, with the utmost prudence, in respect to the kind and quantity of food; but after two or three hours, the pain of head spontaneously ceases. When the stomach itself suffers from irritating ingesta, drowsiness or headach rather quickly succeeds, attended sometimes with confusion of thought and dimness of sight. In such cases, a mild emetic affords immediate relief. In many instances, however, the pain is not felt until several hours have elapsed, and is then accompanied with a sense of tightness and distention of the scalp and stiffness of the eye-balls. Sometimes the patient sees a mist before his eyes, or even luminous and coloured appearances before the headach comes on. Under these circumstances, there is reason to believe that the *duodenum* is principally irritated; an opinion which is rendered probable by the sense of distention and uneasiness which is often felt in the exact situation of that bowel. It is sometimes, indeed, fully confirmed by the fact that an emetic under such circumstances does not afford relief, nor even evacuate any thing material from the stomach; while, on the contrary, a dose of magnesia, either alone or combined with rhubarb or epsom salt, will in two or three hours relieve both the headach, and the uneasiness existing along the course of the *duodenum*. Yet it is proper to add, that when the irritating cause is considerable, both the stomach and *duodenum* remain in a state of disturbance during several hours.

In a very able paper on headach, inserted in the fourth volume of the Medical Transactions of the Royal College of Physicians, Dr. Warren maintains that the headach arising from irritation of stomach differs considerably from that which is produced by disturbance in the *duodenum*; that the former "is attended more with confusion than pain," while the latter is characterized by a dull aching of some parts of the head, "coldness and tightness of the scalp, slight giddiness, weight, pain, distention and stiffness of the eye-balls," and sometimes temporary numbness and tingling of the fingers and hand. Although feeling the greatest confidence in Dr. Warren's accuracy of observation, we have not been able satisfactorily to determine that the latter symptoms may not also occur from irritation of the stomach itself as well as of the *duodenum*; nor are we convinced that the *duodenum* can be irritated to such an extent, by matters which have lately been propelled from the stomach, as to produce a high degree of cephalic irritation, without its contiguous organ, the stomach, being at the same time somewhat implicated in the disturbance.

The exciting or immediate causes of dyspeptic cephalalgia are sufficiently obvious: long fasting; excess in wine or other powerful stimulants; or in the quantity, quality, or variety of solid food, are among the principal. Particular articles of food, likewise, which are innoxious to most persons, become irritating to certain individuals. But it must not be

forgotten that the efficiency of the exciting cause bears an important relation to the amount of predisposition; an article of food, for example, may produce headach to-day, if the stomach or the brain, or both, be unusually excitable, which would not have produced it yesterday when those organs were less susceptible of irritation. Hence the importance of particular investigation with respect to the previous state of the head, as well as of the digestive organs. In many instances it will be found that sedentary habits, excessive mental application, anxiety, the hurry of business, and similar causes, have gradually induced a strong predisposition to headach, although the tendency may not have been developed until some error in diet, acting as the exciting cause, gave rise to gastric disturbance, and thence to sympathetic pain in the head. In truth, a two-fold predisposition may be often said to exist, involving both the head and the stomach. In some cases mental excitement would seem to precede the morbid affection of the stomach. In persons of great susceptibility, a very high degree of cerebral excitation appears to be inconsistent with an adequate supply of nervous energy to the digestive organs; as if there were but a certain portion of vigour to be shared by the different parts of the system, and, consequently, that an undue proportion allotted to one occasioned a corresponding deficiency in the rest. The fact, however, is incontrovertible, that, in many susceptible individuals, intense engagement of mind induces a powerless state of stomach and *duodenum*, giving rise to dyspepsia, and the headach arising from it.

Not uncommonly cerebral excitement occasions a rapid and profuse secretion of bile, which, in its turn, produces a sick or bilious headach in its severest form. We have repeatedly seen the same effect follow an unusual degree of bodily exercise; in which case, it is sometimes attended with both vomiting and purging of a highly bilious character.

The dyspeptic cephalalgia chiefly occurs in early or in middle life, becoming less and less severe as the irritability of the system gradually declines. Sometimes, however, as life advances, there is an apparent transfer of irritability from the stomach to the bowels. Frequent diarrhœa takes the place of bilious headach, being excited by the same circumstances.

The treatment of dyspeptic headach requires a careful adaptation to the peculiarities of each case. An ordinary paroxysm of the pain, if attended with much nausea, may be considerably shortened by an ipecacuanha emetic, afterwards allowing to the stomach and to the head an interval of entire repose. After an hour or two, twenty or thirty grains of magnesia combined with rhubarb, or the sulphate of magnesia and an aromatic, may be given, and followed, after some hours, by a little bland farinaceous nourishment. Where no particular nausea is felt, the antacid aperient may be given at the first. A few grains of the subcarbonate of ammonia, or thirty or

forty minims of the aromatic spirit of ammonia, may be added with advantage, when the stomach is peculiarly irritable.

In the milder and more chronic forms of dyspeptic headach, much will depend on the discipline of the mind and the regulation of the table. Every individual may be able, by proper attention, to ascertain what kinds of food and what quantity of food he can comfortably digest; and under what particular circumstances the symptoms of indigestion and headach have generally arisen.

A little observation will also discover the connexion which subsists between that state of tone and vigour of the whole system which regular bodily exercise induces, and the power of the stomach itself. Thus it will be found that the same kinds and quantity of food which perfectly agree while the individual takes his daily walk in the open air, and employs his brain within moderate bounds, become sources of indigestion and headach when the head is allowed too much duty and the feet too little.

The daily management of the bowels is an object of great importance in this kind of headach. When diet and exercise prove insufficient to secure a daily motion, a mild stomachic aperient, combined, perhaps, with an alkali, may be given every night, or on alternate nights, until the tendency to constipation and headach be overcome. When, however, there appears to be much *duodenal* indigestion, a few grains of rhubarb, or of a grain or two of aloes, taken before dinner, will be a preferable mode of increasing the propulsive power of the intestines. We cannot, however, recommend this as a general mode of regulating the bowels; being convinced that it often accelerates, in an injurious degree, the peristaltic action, and deprives the system of a part of the nourishment which would otherwise be received by absorption. Persons have been found to become manifestly thinner under such a plan. When, as indeed often happens, the biliary secretion is irregular or defective, a mild mercurial preparation may be given for a few successive or alternate nights. Occasionally some aromatic bitter, either with or without soda or ammonia, may be employed with advantage. Horse-exercise, if it be not used to the exclusion of walking, is often extremely beneficial. The shower-bath, or cold sponging, aided by friction of the skin and moderately warm clothing, are also powerful auxiliaries.

VI. Cephalalgia periodica.—This kind of headach is said to be sometimes hereditary. It may have regular or irregular accessions, and may occur in a quotidian, tertian, or quartan form. It has returned periodically at the regular intervals of several weeks or even months. Most commonly it observes daily accessions, returning either in the morning or at noon. Sometimes a very limited portion of the head, a small spot, is alone affected. Not unfrequently the pain commences at the inner angle of the orbit, producing pain, redness, and tenderness of the eye, and extending towards the nose. This has been popularly

called *megrim*. In other instances, one entire half of the head and face is affected, constituting the *hemicrania* of authors. The pain is sometimes so acute as to resemble that of tic douloureux; but it may generally be distinguished from the latter by its more regular periodical accessions, by the longer duration of each paroxysm, and by the more complete and protracted intermissions. In many cases, too, the periodic cephalalgia is obviously connected with existing rheumatism or catarrh. The pain of tic douloureux, on the other hand, is generally very sudden in its attack, and quite excruciating in its degree, but lasts only for a few seconds. It returns at indefinite periods, being readily excited by the slightest exposure to a current of air, or by the motion of the jaws in eating or speaking. The cephalalgia periodica also bears some resemblance to the muscular or simply rheumatic headach; from which, however, it may generally be distinguished by the greater regularity of its accessions; by its usually affecting a circumscribed portion, or, at most, one side of the head and face; and more particularly, by its frequent connexion with intermittent fever. Sometimes, indeed, it appears to be the direct effect of an exposure to malaria, although unattended with the ordinary phenomena of fever. In other instances, a carious tooth or some lesion of the antrum highmorianum has appeared to produce and maintain the disease. Accordingly, the extraction of the afflicted tooth has entirely removed the cephalalgia.

As in every other species of headach, a careful consideration of the peculiarities of each individual case can alone lead to a discriminating and successful treatment. Where no local irritation can be traced, and no congestive symptoms about the head appear, cinchona in substance, or the sulphate of quinine, may be exhibited in the intervals, as soon as the bowels have been thoroughly cleansed by a dose of calomel conjoined with rhubarb, jalap, or some other effective purgative. In some peculiarly obstinate cases, it may be right to have recourse to the arsenical solution, preserving, at the same time, a regular state of bowels by some mild aperient, in combination with the pilula hydrargyri or the compound pill of the submuriate of mercury. Where the paroxysms are extremely violent, much relief may be often gained by a full opiate conjoined with the compound spirit of sulphuric ether, given just before the expected accession. In the more limited forms of the periodical cephalalgia, the extracts of belladonna and opium, applied to the part affected, sometimes afford considerable mitigation.

(T. H. Burder.)

HEART, DISEASES OF THE.—Diseases of the heart were, until recently, supposed severally to present symptoms of very much the same general character, and therefore to constitute a class of maladies which possessed considerable unity in their intrinsic nature. They are now, however, found to consist of a variety of distinct affections producing very

different and sometimes opposite symptoms. Thus, hypertrophy produces increased, and dilatation diminished force of the circulation. In order, therefore, to appreciate the value, and familiarize ourselves with the nature, of each class of symptoms, it is necessary to study the several affections in an isolated form. We are thus enabled, on meeting with a *compound* case—one consisting of a complication of several of the simple affections—to analyse or unravel the symptoms, ascertain the relative importance of each class, and in this manner establish rational and secure principles of treatment. In conformity with this view, the various articles on the diseases of the heart, instead of being assembled under the present head, are, for facility of reference, diffused alphabetically throughout the work. We have here only to put the whole together in a systematic form, so as, by pointing out the affinities from detached articles, to enable the student to prosecute his studies in a consecutive form, and to find with facility any given article or topic to which he may wish incidentally to refer.

Physiology of the heart's action, and physical signs—healthy and morbid. In the article *AUSCULTATION* will be found a sketch of the physiology of the heart's action according to the principles of the writer, adopted throughout this work, and a general exposition of the principles of auscultation in reference to the heart. A more particular and differential account of the signs afforded by auscultation and percussion will be found in the several articles to which the signs respectively refer: viz.—in the article *HYPERTROPHY OF THE HEART* are all the signs characterizing this affection, whether simple or combined with dilatation. In *DILATATION* are the signs of the simple and the attenuated forms of the disease; the other forms, with their signs, being comprised under *HYPERTROPHY WITH DILATATION*. In *DILATATION* the *range of sound*, and in *HYPERTROPHY* that of *impulse*, is more particularly described. Under *VALVES, DISEASES OF THE*, are the signs of all the varieties of this affection, with the diagnosis from analogous signs produced by nervous derangements; under *AORTA, ANEURISM OF THE*, are the signs of disease of the great vessels, with the diagnosis from nervous affections; and under *MALFORMATIONS* and *POLYPUS* are the peculiar signs, according to the writer's observation, of those maladies.

We would recommend the student to adopt the following arrangement of the articles in studying the various diseases of the heart consecutively. Inflammatory affections of the heart and great vessels, as they give birth to a large proportion of the organic diseases, should take precedence of the rest. Thus *PERICARDITIS* leads to *ADHESION OF THE PERICARDIUM*, (which subject is discussed at the end of *PERICARDITIS*); and the latter leads to *HYPERTROPHY WITH DILATATION*. *CARDITIS* (which is treated of under *PERICARDITIS*) gives rise to *SOFTENING, INDURATION, DILATATION*. *ARTERITIS*, acute and chronic, contains an account of the morbid alterations of the valves and internal membrane of the heart and arteries, to

which it gives origin. Under this head, also, the other probable causes of some of these alterations are fully discussed. *HYPERTROPHY* should next be studied. It embraces the varieties in which it is conjoined with dilatation. After reading this article the student should proceed to *DILATATION*, in order that, by contrasting the respective varieties, the mode of production, and the pathological effects of hypertrophy and of dilatation, he may be enabled to form a just and comprehensive idea of the relative nature of the two affections. *DILATATION* presents an account of those varieties only in which the force of the heart's action is *not* increased: viz.—*DILATATION WITH ATTENUATION*, and some cases of *SIMPLE DILATATION*; those in which the action is increased being described under *HYPERTROPHY WITH DILATATION*. After reading *HYPERTROPHY* and *DILATATION*, the student should proceed to *VALVES, DISEASES OF THE*, as he is now prepared to understand how these produce their effects, and become causes of hypertrophy and of dilatation. *VALVES, DISEASES OF THE*, comprehends every variety of these affections, with the signs physical and general; and also an account of cardiac asthma. The following diseases of the muscular structure may next be studied: *PARTIAL DILATATION, OR REAL ANEURISM OF THE HEART; SOFTENING; RUPTURE; INDURATION; FATTY AND GREASY DEGENERATIONS; PRODUCTIONS, ACCIDENTAL; ATROPHY OF THE HEART. AORTA, ANEURISM OF THE*, comprising an account of nervous pulsation of the aorta, forms an elaborate article, much original matter being added with a view to establish the diagnosis—one of great importance, and now, we trust, presenting little obscurity: the study of this subject should be deferred till the reader is acquainted with *HYPERTROPHY, DILATATION, and VALVES, DISEASES OF THE*, as he will thus be better qualified to understand how disease of the aorta gives birth to that of the heart, and constitutes one of the most formidable complications of cardiac affections. *MALFORMATIONS, ANGINA PECTORIS, POLYPUS OF THE HEART, DISPLACEMENTS, HYDRO-PERICARDIUM, PNEUMO-PERICARDIUM, PALPITATION*, particularly nervous and dyspeptic, are severally brought under consideration in separate articles.

Treatment.—In the article *PERICARDITIS*, the treatment of the inflammatory affections is fully considered. A few remarks are also appended to *ARTERITIS*. In *HYPERTROPHY* and *DILATATION* respectively, the observations on treatment are confined to the immediate and peculiar effects of each disease; while *VALVES, DISEASES OF THE*, is a general article on treatment, not only embracing all the secondary effects, but giving a detailed account of the manner of exhibiting, and the *modus operandi* of the various remedies employed. In *AORTA, ANEURISM OF THE*, the mode of spontaneous cure and the medical treatment are fully explained, and remarks are added on the treatment of nervous aortic pulsation.

We shall conclude this brief explanatory and indicatory notice with a few remarks on

the diagnosis and treatment of cardiac affections in general.

Diseases of the heart were formerly involved in deep obscurity. This is no longer the case. By a *conjunction* (and the necessity for this conjunction cannot be too strongly impressed) of the *physical* signs, or those afforded by auscultation and percussion, with the *general* signs, improved as they have been in consequence of being studied with the aid of auscultation, the diseases in question may be detected with a facility and precision which can scarcely be surpassed in any other class of affections. The *direct* practical advantage resulting from this is, that instead of being almost incurable, as they were formerly regarded in consequence of seldom being detected till they had attained an incurable degree, they now, from admitting of detection even in the earliest stage, can in numerous instances be completely cured; and when not, can in general be so far counteracted as not materially, and often not at all, to curtail the life of the patient. The *collateral* practical advantages are no less important. Apoplexy and palsy, in a scarcely credible number of cases, are directly dependent on hypertrophic enlargement of the heart. Should the cause be detected, the effect may be obviated; should it be overlooked, the patient would probably fall a martyr to the "active exercise" supposed necessary to reduce his *apoplectic fulness of habit*. No less frequently are the most dangerous cases of asthma, of dropsy, and of epilepsy, referable to disease of the heart; and this malady seldom occasions long-continued obstruction of the circulation without producing enlargement of the liver,—one of the least generally known of the common facts in medical science. Nervousness and dyspepsia very often assume the aspect of disease of the heart; and this, on the other hand, being frequently productive of nervousness and dyspepsia, may be disguised by, and mistaken for them, though with the aid of auscultation the diagnosis presents no difficulty. In acute rheumatism the most formidable source of danger is inflammation of the pericardium. Inflammation of the lungs supervening on organic disease of the heart is singularly rapid, uncontrollable, and destructive. In fever and inflammation in general, the state of the pulse as to fulness, hardness, weakness, or irregularity, may be completely disguised by a co-existent disease of the heart. In all the above instances the appropriate treatment would differ widely and perhaps entirely from that which the practitioner would probably adopt were he to remain ignorant of the affection of the heart.

This brief sketch is sufficient to display the extensive relations and vast importance of the subject of cardiac affections, and to show, that unless the practitioner be conversant with it, not only may he compromise the safety of his patient, but his reputation must be responsible for many mortifying falsifications of his diagnosis, and for the blind impression that danger was remote when it was at the threshold.

(J. Hope.).

HEART, DISPLACEMENT OF.—*Ectopia cordis*, from *ἐκτοπίζω* or *ἐκτόπιος*, displaced. The human heart, when occupying its natural position, is situated in the left side of the thorax, behind the sternum and cartilages of the true ribs, and between the right and left lungs. In this situation it is placed obliquely, so that if a line were passed through its axis at the moment of its pulsation, its direction would be downwards, forwards, and to the left side. Its base is placed almost directly opposite the eighth dorsal vertebra, from which it is separated by the œsophagus and aorta, while its apex is turned forwards and obliquely over to the left side; so that it corresponds, when in a state of repose, to the cartilage of the sixth true rib, and strikes during its pulsation between the cartilages of the fifth and sixth left ribs, at a point about two inches below the nipple, and one inch on its sternal side. The inferior or posterior surface of the heart is flat, and rests upon the tendon of the diaphragm, which supports it; its superior or anterior surface is convex, and is overlapped by the anterior edges of the lungs. From this, which may be considered the natural position of the heart, numerous forms of deviation have been observed, from a slight alteration in the direction of its apex, to the total displacement of the organ from the interior of the chest.

Displacement of the heart may occur as a *congenital malformation*, or as the *result of accident or of disease*.

I. Some of the congenital displacements are very similar to those into which the heart is sometimes forced by diseases of the pleura or lungs, or even by certain organic affections of the heart itself; others, again, are liable to be mistaken for aneurismal tumours or other organic diseases of the heart or large vessels, and might, therefore, mislead the physician into the most serious errors of diagnosis, and consequently of practice, if the possibility of their occurring as a congenital malformation were not borne in mind. For this reason we shall give a succinct account of the principal congenital displacements of the heart, referring the reader who wishes for more ample details on this interesting subject to the excellent "*Mémoire sur l'ectopie du Cœur*," published by M. Breschet in the second volume of the "*Repertoire Général d'Anatomie*," and to Dr. Paget's "Inaugural Dissertation on the Congenital Malformations of the Heart."*

The congenital displacements of the heart may be divided into two classes: the first comprising those cases where the heart is contained within the chest, but does not occupy its natural situation there; the second containing those cases of malformation where the heart is situated out of the cavity of the thorax.

Cases of this description, though of not very unfrequent occurrence, from the slight inconvenience they occasion, have received comparatively little attention; yet from the

* Edinburgh, 1831.

resemblance they bear to the displacements produced by disease, they are, perhaps, the most interesting and important to the practical physician. The following are the principal deviations from its natural position dependent on congenital malformation, which the heart presents while still situated within the thorax.

Instead of being placed diagonally to the axis of the body, with its apex pointing to the left side, it may be situated, *a.* horizontally; *b.* vertically, with its apex pointing downwards; *c.* vertically, with its apex pointing upwards; *d.* diagonally, with its apex pointing to the right instead of the left side; or *e.* transposed altogether to the right side of the chest.

a. The heart has, we are informed, been found in the horizontal position;* but this deviation is of very rare occurrence as a congenital malformation, and it may perhaps be doubted whether the effects of disease have not been mistaken for such. We shall presently see that this alteration in the position of the heart is, as was remarked by Bertin, constantly produced by the enlargement of that organ from hypertrophy.

b. The heart has occasionally, though very rarely we believe, been found in the centre of the thorax, occupying a vertical position, as in quadrupeds. A case of this kind is described by Breschet.† The infant was born at the full time, lived six weeks, and exhibited no external malformation: the heart, which was composed of a single auricle and ventricle, was situated exactly in the median line of the thorax, its apex having a slight inclination towards the left side. Another case, described by Klinn,‡ is usually quoted as an example of this species of malposition; but there can be little doubt, even from his own description, that the displacement of the heart was caused by the pressure of an effusion which had taken place into the left sac of the pleura.

c. A much greater alteration in the position of the heart, where the organ was so completely subverted that its basis was inferior and its apex superior, is related by Ignatius de Torres. "In a new-born female infant, the heart, destitute of a pericardium, was turned upside down, so that its basis with all the great vessels had fallen down as low as the navel, and its apex, still in the left side, lay hid between the two lungs."§

d. The direction of the apex of the heart to the right side, and the situation of the entire organ more or less to the right of the mesial line, is among the most common of the situations which the heart occupies when out of its usual place.

e. Breschet dissected four cases in the Foundling Hospital at Paris, where the heart

was situated at the right side, without any of the other viscera being transposed.* Otto,† Moellenbrock,‡ Mohrenheim,§ and Elvert,|| have likewise described this species of congenital displacement.

In the greater number of cases where the heart is placed from birth at the right side, there is also a similar transposition of the other thoracic and of the abdominal viscera. A case highly illustrative of this general transposition of the viscera is recorded by Dr. Bryan in the Transactions of the College of Physicians of Dublin, and the specimen is preserved in the superb museum of the College of Surgeons of that city.

The apex of the heart, instead of pointing towards the left, corresponded to the interval between the fifth and sixth ribs of the right side; its auricles and ventricles occupied a position exactly the contrary of their ordinary relative situations; and the aorta, which gave off those vessels to the right that it usually furnishes to the left, descended along the right side of the vertebral column. The left lung was divided into three lobes, while the right had only two. The pyloric orifice of the stomach was turned towards the left hypochondrium, which was occupied by the liver, the spleen being at the right side. The whole intestinal tube was transposed in like manner, the caecum resting on the left iliac fossa, &c. &c. In short, all the parts usually situated at the right side were placed at the left, and *vice versa*.

The subject of this case, we are informed, was a woman advanced in life, who had borne several children, and enjoyed good health until a short time before her death. The appearances found on dissection in the kidneys, uterus, and bladder, sufficiently accounted for the symptoms under which she suffered; but no suspicion was entertained that there existed any thing peculiar in her conformation, nor did the displacements lead to any particular symptom—not even to a preference of using her left hand.

We have been informed by Dr. Kenedy that a respectable middle-aged female presented herself last summer at the Dublin General Dispensary, complaining of dyspnoea and distressing palpitations. On examination with the stethoscope, it was discovered that the heart was pulsating at the right side, and no disease could be detected in any of the thoracic viscera to account for the displacement; in addition to which the woman positively avowed that she had felt her heart beating in the same place as long as she could remember. The physician to whom we are indebted for these particulars seemed to entertain little doubt that the displacement in this case was congenital.

The second class of congenital displace-

ments of the heart, comprising those cases of malformation in which that organ is situated out of the cavity of the chest, may be divided into those where the heart is situated on the surface of the body, and those where it is situated in the interior, but not in the thorax.

"The first kind, in which the heart is on the outside of the body, includes some of the most fatal as well as most frequent cases of exposition of this organ. It is generally connected either with deficiency in the diaphragm and abdominal muscles, or with absence of some part of the walls of the thorax. In the former case, we generally find the heart, liver, and stomach, and often the lungs, and all the abdominal viscera, contained in a sac, sometimes covered only by peritoneum,* sometimes by an extension of the common integuments,† and sometimes occupying the sheath of the umbilical cord,‡ forming a variety of umbilical hernia."§

Protrusion of the heart may likewise take place through a fissure, or deficiency in the sternum or ribs. Some cases of this description are quoted by Breschet in the *Mémoire* already so often alluded to; they seem to have arisen principally from a deficiency in the lower part of the sternum from the imperfect development of that bone, and were not accompanied with any other malformation. Such cases are, however, exceedingly rare in comparison with those where the fissure of the sternum and the protrusion of the heart through it is accompanied with other malformations arising from a defective development of the parietes of the different cavities from the circumference towards the centre, such as large apertures in the parietes of the chest and abdomen with hernia of their contents, spina bifida, cleft palate, hare-lip, open perineum, &c.

When the heart is situated in the interior of the body, but not within the chest, it may be found either in the abdomen or in the neck.

Heart situated in the abdomen.—Ramel relates the case of a girl ten years of age, whose heart was placed from birth below the diaphragm, in the situation usually occupied by the stomach. During infancy she did not appear to suffer any inconvenience from the malposition, and as she grew up it was only on crying violently, or using any particular exertion, that she was seized with palpitations, dyspnœa, and occasionally with epistaxis. Ramel attended her for two years, during which time her health and strength continued to improve, until it seemed at length as if nature had become completely reconciled to this unusual arrangement of the circulating system.|| Another case of this species of malposition of the heart was found by Doctor Wilson in an infant seven days old.¶ The central and tendinous portion of the diaphragm was deficient, as was also the inferior portion

of the pericardium. The heart, consisting of a single auricle and ventricle, was lodged in a deep groove on the convex surface of the liver. In this case there were several other malformations of the principal bloodvessels, as well as of the abdominal viscera, which were sufficient to account for the death of the individual, independently of the displacement of the heart. But the most extraordinary case of this kind on record is that related by M. Deschamps,* where *the heart was found occupying the place of the left kidney*. The individual in whom this malformation was found was an old soldier who had served several campaigns, and enjoyed excellent health, with the exception of nephritic pains, to which he had then been for some years subject, and on account of which he eventually obtained his discharge from the service. Notwithstanding the frequent recurrence of these pains, he married, and became the father of three children; at length, however, the symptoms of renal disease became more violent, and recurred more frequently; hectic fever set in, and he died after an agony of forty hours; his abdomen covered with large gangrenous spots. On dissection, the right kidney was found very large and in a state of suppuration; the place of the left kidney was occupied by the heart, enveloped in its pericardium. In the thorax, there was no trace of the heart to be found, nor was there any appearance to indicate its ever having been placed there. It is remarkable that this extraordinary displacement of the heart was never discovered or even suspected by the individual or his medical attendants, all the functions of the heart being as effectually and as regularly performed as though it had occupied its natural position within the thorax. It does not appear that there was any malformation of the diaphragm, or indeed of any other part in this instance.

Heart situated in the neck.—In M. Breschet's excellent *Mémoire* on this subject, three cases of this extraordinary malformation, which he proposes to designate *ectopia cordis cephalica*, are related. In one of these cases the heart, lungs, and thymous gland, were all situated in the front of the throat, where they formed a large tumour immediately underneath the lower jaw. The apex of the heart was attached to the base of the tongue, and lay between the rami of the inferior maxilla. The chest was filled with the abdominal viscera, which had passed up through an aperture in the diaphragm. As such complicated malformations are manifestly incompatible with the extra-uterine life of the individual, their description can afford little practical interest to the physician; we shall, therefore, content ourselves with thus briefly noticing the existence of this variety of congenital displacement, and refer the scientific anatomist to the original essay on the subject by M. Breschet.

Without entering at length into the causes of the different varieties of congenital malposi-

tion of the heart, which would be the more unnecessary as the subject will be fully considered in a separate article on MALFORMATIONS of that organ, we may remark in general terms, that the greater number of these congenital misplacements depend on an arrest of development at a period before the evolution of the fœtus is completed. In this way may be explained the imperfect union of the parietes of the different cavities, and the consequent displacement of the organs usually contained within the thorax and abdomen, their protrusion out of these cavities, &c.; to this cause may also be attributed, with considerable probability at least, the situation of the heart in the neck; as all writers on the development of the embryo are agreed that the heart is situated immediately underneath the head during the first period of the evolution of the fœtus, and that the aorta, instead of forming an arch, descends directly into the chest. It is obvious that if the development of the heart be arrested at this early period, the organ will remain out of the thorax, in the anterior part of the throat, as in the *ectopia cephalica* of Breschet.

We must not, however, suppose that all congenital misplacements of the heart may be thus accounted for, as there are some which evidently result from a perversion of the natural order of development: to this class belong the inclination of the heart's apex to the right, and the total transposition of the organ to that side, accompanied, as it usually is, with a similar transposition of the other viscera. In this way, also, we must explain the situation of the heart in the place of the kidney in the remarkable case recorded by Deschamps, inasmuch as the organ never occupies that position at any period of the evolution of the fœtus, and, *a fortiori*, could not continue to occupy that position in consequence of an arrest of its development; neither was there any malformation or disease of any of the neighbouring viscera to account for the displacement.

II. Displacement of the heart may likewise be occasioned at any period of life by accident or by disease. Displacement from the former cause seldom falls under the observation of the physician, as any accident which is of sufficient violence to force the heart out of its natural situation seldom fails to prove instantaneously fatal. Indeed, the only recorded exception that we are aware of is furnished in the remarkable "case of probable dislocation of the heart from external violence," published by Dr. Stokes in the *Edinburgh Medical and Surgical Journal*, No. 103, from which we copy the following account:

"Mr. B., æt. 21, had enjoyed uninterrupted health until the 7th of May, 1822, when he was severely crushed between a water-wheel and the embankment on which the axle was supported. He remained for three hours after the accident in a state of complete insensibility. As soon as an examination could be made, the following injuries were discovered. Two ribs in the lower portion of the left side, the right clavicle and humerus, and the fifth, sixth, and seventh ribs on the right side, were broken. The

right side of the face and chest was emphysematous, and there was complete paralysis of motion in the right arm, with considerable loss of sensation. *The patient felt great pain in the right side of the chest, with a sensation as if a foreign body preventing respiration had been introduced into the right lung: the pain was accompanied with violent throbbing and heaving, and it was soon discovered that his heart was pulsating at the right side of the sternum.* He had a short dry cough, but experienced no hemoptysis; and there was no pain or other symptom of pleuritic inflammation at the left side,—a point of considerable importance in the diagnosis of the lesion.* From that period to the present his heart has continued to pulsate on the right side of the sternum, the pulsation being generally strong, and aggravated by mental emotion, exercise, or the occurrence of pain in the side. He has never had orthopnoea, but has always experienced great difficulty of breathing on exercise, or when he has attempted to lie on the left side. Since the accident he has every winter experienced several inflammatory attacks, in which he suffers from violent pain of the right side, with great increase of palpitation and dyspnoea. These attacks are only relieved by bleeding, and he thinks he has been bled upwards of fifty times. It is a remarkable circumstance that syncope has never been produced even after the loss of so much as thirty ounces of blood at a time, and that he has taken the powder of digitalis in the dose of eight grains every night for the space of three months, without his pulse ever descending below eighty. When he does not take digitalis, his pulse is generally between one hundred and one hundred and twenty, regular in strength and never intermitting; but when he uses that remedy in his ordinary state, the number of respirations is about thirty in the minute. His habit of body is spare but muscular, and the countenance is not expressive of pain. From August to the latter end of April last he shared constantly in the sports of the field: hunting and shooting were his constant employments.

"On stripping the patient and examining his chest carefully, the right shoulder appears depressed, but the right side inferiorly measures an inch in circumference more than the left.

"The left side of the thorax sounds perfectly clear, even to its most inferior portion, and in the situation usually occupied by the heart. Respiration of the puerile character, and mixed with some bronchial râles, is to be heard over the entire lung, and is as distinct in the mammary region as in the other portions. Neither the sound nor impulse of the heart is perceptible in the cardiac region. At the right side the upper portion of the lung

* We had lately an opportunity, through Dr. Stokes's kindness, of examining this patient, and of ascertaining the accuracy of the above statement. The patient, when interrogated, stated without the least hesitation, that before the accident his heart had always beat at the left side, and that he was himself the first to notice its change of position after that event.

sounds clear, but from the fifth rib downwards there is complete dullness, and here the integuments are exquisitely sensible. In the upper portion, both anteriorly and posteriorly, the respiratory murmur is of the same character as in the opposite lung, but from the fifth rib downward it is wanting; there is no bronchial respiration or resonance of the voice. The pulsations of the heart can be seen and felt in the right mammary region, between the sixth and seventh ribs, and within an inch of the sternum. When not over-excited the sounds of the heart are almost natural. There is no sign of valvular disease."

That the heart was actually displaced in this case, there can be no doubt whatever; and that the displacement was caused by the external injury is rendered highly probable, from the fact of its being observed for the first time almost immediately after the accident, and from the absence (as ascertained by auscultation and percussion) of all those diseases of the adjacent parts which usually cause the displacement of the heart from the left to the right side.

Besides the causes of displacement already enumerated, viz. congenital malposition, and accident or external injury, the heart is likewise liable to be forced out of its natural situation by various morbid alterations of the adjacent parts.

On studying the anatomical relations of the heart, we perceive that it is retained *in situ* by the large bloodvessels which form its superior attachment,—by the adhesion of the pericardium to the diaphragm, which attaches it inferiorly,—and by the walls of the mediastinum and the equal pressure of the lungs, which oppose its displacement to either side. But as none of those forces which retain the heart in its natural position is of a fixed or unyielding nature, it follows that, whenever a degree of pressure sufficient to overcome their resistance is exerted on the heart by the enlargement or other morbid alteration of any of the surrounding parts, that organ is pressed out of its natural situation, and forced upwards or downwards, to the right or left side, according to the direction in which the pressure is exerted.

The following are the diseases which have been observed most frequently to cause displacement of the heart.

1. *Effusion into the sac of the pleura.*—In nine cases out of ten where the heart is removed out of its natural situation, the displacement will be found to have arisen from empyema or pneumothorax; accordingly this displacement is now generally regarded as the most constant and least fallible symptom of these diseases. Of twenty-seven cases of empyema and pneumothorax that have come under the author's observation in the extensive hospitals attached to the Dublin House of Industry, the heart was perceptibly displaced in every instance. Pathologists have long remarked that effusion into the left pleura, by the pressure which it exerts on the parietes of the cavity, as well as on the organs contained within it, is capable of thrusting the heart over

to the right side of the sternum; but they do not seem to have been aware that effusion into the right side, by protruding the mediastinum and pressing on the heart, may cause a very considerable displacement of that organ to the left of its natural position. In a case of pleuropneumothorax, with fistulous communication through the lung of the right side, which was lately operated upon by Mr. Mac Dowel, in the Richmond Hospital, the heart was distinctly seen and felt pulsating between the fourth and fifth ribs, near the left axilla, from which situation it gradually returned to its natural position, as the pressure which caused its displacement was removed by drawing off the air and fluid from the opposite side. In all cases of extensive effusion, whether of air or fluid, into the pleura of the right side, we have uniformly observed a similar displacement of the heart proportioned to the extent of the effusion. This displacement of the heart to the left can in some cases only be detected by minute examination, and even in extreme cases is less likely to attract observation than the displacement to the right of the sternum, which seldom fails to arrest the attention of the patient, even though it should be overlooked by his medical attendant. We have already entered at length into the consideration of the value of this symptom as indicative of effusion into the pleura, and shall therefore refer the reader to the article *EMPHYEMA*, where he will find this subject fully considered.

2. *Aneurism of the aorta.*—When tumours of this kind come in contact with the heart, they seldom fail, as they increase in size, to force it to a greater or less distance from its natural position. Dr. Hope records a case of aneurism of the ascending aorta displacing it to the left. The writer has seen an instance of aneurism of the arch thrusting the heart downwards, so that its apex pulsated in the epigastrium. It is evident from their relative anatomy that aneurism of the thoracic aorta may cause displacement of the heart according to the direction which the sac takes; and Drs. Graves and Stokes have shewn that considerable displacement of the central organ of the circulation may be produced by aneurism of the abdominal aorta pressing up the diaphragm and pericardium. In the interesting case which they have recorded, "the heart was at first found to beat in the epigastrium, the impulse having left the usual situation. In the course of a few days it became feebler in the epigastrium, but could be felt pulsating on the right side, at the sternal end of the fifth rib, and ultimately became fixed in the intercostal space of the third and fourth ribs."*

We may remark that in two cases of aneurism of the ascending aorta which we had lately under our care, the sac presented a double sound at each pulsation: in neither case was there any perceptible displacement of the heart, as the tumour took a direction upwards and to the right side; but in one of the cases which we subsequently had an op-

* Dublin Hosp. Reports, vol. v. p. 10.

portunity of inspecting, we ascertained that the aneurism was in actual contact with the pericardium and heart, from which no doubt it received and transmitted the double pulsation. In two cases related by Drs. Graves and Stokes,* the aneurismal tumour gave a double pulsation; and we believe that a similar phenomenon will be observed whenever the aneurism is so situated as to have the double stroke of the heart mechanically communicated to it.

3. *Tumours*.—Tumours of every description developed in the vicinity of the heart, when they take such a direction and attain so great a size as to press upon that organ, may mechanically displace it. In a young woman who died in the Hardwicke Fever Hospital with symptoms of acute thoracic inflammation, we found on dissection, at which we were assisted by the late Professor Bennet, a large *encephaloid* tumour, which appeared to have originated in the bronchial glands situated at the root of the left lung, and thence to have descended between the pleura and pericardium, thrusting the heart over into the right side, and eventually eating its way by ulceration through the pericardium, where its irruption excited violent inflammation. A similar displacement of the heart, and apparently from a similar cause, was found by Boerhaave on the dissection of the Marquis de St. Auban.†

4. *Pulmonary emphysema*.—Laennec states, "that when a single lung is affected, it sometimes becomes so much more voluminous than the other as to press aside the heart and mediastinum."‡ Judging, however, from our own experience, we feel inclined to rank this among the least frequent causes of displacement of the heart, as in most instances where one lung is sufficiently emphysematous to produce such an effect, the other participates in the morbid alteration, and by its increased volume maintains the pressure which the heart sustains in equilibrium: such at least we have found to be the case in the numerous dissections that we have made.

5. *Diaphragmatic hernia*.—It is evident that when the abdominal viscera are forced into the thorax through an opening in the diaphragm, they may exert such a degree of pressure on the heart as to force it from its natural position. This species of hernia is often congenital, and arises from imperfect development of the diaphragm, in consequence of which an aperture is left, through which several of the abdominal viscera are protruded into the chest by the contraction of the abdominal muscles. We have already recorded examples of congenital ectopia from this cause. It seldom happens that such subjects survive longer than a few hours after birth, in consequence of the obstruction which the respiration encounters. Instances, however, are not wanting of life being prolonged for a considerable period under these apparently hopeless circumstances. In Dr. Wilson's

case already quoted, the infant lived some days; but decidedly the most interesting case of this description on record is related by Drs. Graves and Stokes.

"A man about forty years of age died of tubercular phthisis. The œsophagus, after passing through the usual opening in the diaphragm, was found to re-enter the thorax by another very large opening in the tendinous portion towards the left side. The stomach occupied the inferior portion of the left thoracic cavity, its cardiac and pyloric orifices both lying in the opening. A considerable portion of the transverse arch of the colon was also included in the left side of the chest: these viscera, loosely but permanently fixed by means of the serous membranes, all rested on the convex surface of the diaphragm, and *pushed the heart and mediastinum towards the right side.*"* There seems little doubt that the hernia in this case was the result of congenital malformation. Hernia of the abdominal viscera into the thorax, and consequent displacement of the thoracic viscera, has likewise been caused by wounds of the diaphragm,† by rupture of that septum occasioned by a fall; by great exertion;‡ and, as has been alleged, by enormous distention of the stomach.§

6. *Enlargement of the liver*.—This is also enumerated by authors among the occasional causes of displacement of the heart; we are not, however, acquainted with a well authenticated instance of the kind. It is probable that a considerable hypertrophy of the left lobe may elevate the diaphragm and displace the heart; the same effect may likewise be produced by excessive enlargement of the spleen, or by the development of any morbid growth in the epigastrium or left hypochondrium.

7. *Hypertrophy with dilatation of the heart*.—When the heart is enlarged, its apex is carried to the left, and its basis to the right side, in such a manner that it lies almost transversely across the chest. This observation, originally, we believe, made by M. Bertin,|| has been repeatedly verified by the writer. It has also been remarked by Bertin that in those cases where the size and weight of the heart are very considerably augmented, the organ presses with all its weight on the diaphragm, so that that portion of the septum on which it reposes is thrust before it like a pouch in the abdomen. Sometimes this depression has been known to take place without any visible cause, in which case the affection has received the name of *prolapsus* of the heart.¶ Some authors have thought that this prolapsus might be caused by relaxation of the vessels, by which the heart is as it were suspended in situ.** We think it more probable, however, that the displacement in such cases must have been more apparent

than real, as we know from experience that the heart's pulsation may be felt in the epigastrium in a great many persons, particularly when the sternum is short, although the heart retains its natural position.

Diagnosis and treatment.—Displacements of the heart are now easily detected by the aid of auscultation and percussion: the disappearance of the usual phenomena of the heart's action from the cardiac region, and their appearance in another and different situation, afford unerring evidence of a corresponding change in the position of the organ. As, however, the changes of position which the heart undergoes are, in every instance almost, the effect of more serious organic lesions, their diagnosis becomes a matter of very secondary importance, as compared with that of the disease by which they were caused, and of which they should properly be regarded as a symptom. Indeed, the principal advantage, in a practical point of view, of detecting a displacement of the heart, is derived from the light which it throws on the nature, extent, and situation of the primary disease by which it was produced, and on which the danger of the displacement, as well as its appropriate treatment, in a great measure depends. It is therefore to the accurate diagnosis of the cause of the displacement that the scientific physician will chiefly direct his attention; these causes we have already enumerated, and we beg to refer the reader to the respective articles which treat of the particular diseases, for such diagnostic characters as may enable him to decide in any doubtful case the true cause of the displacement.

From the circumstance of displacement of the heart being so constantly combined with other and more serious lesions, it is extremely difficult to ascertain the effects on the system resulting from the simple displacement. In *congenital malpositions* the alteration in the heart's place is usually coupled with other malformations of a more serious character, which either cut short the life of the individual, or else complicate the symptoms of the displacement in such a way that it is impossible to analyze them correctly. In those rare cases where the displacement of the heart was the principal or only deviation from the natural arrangement of parts, little or no inconvenience seems to have resulted from it. In Ramel's case already quoted, where the heart was situated below the diaphragm, the individual experienced no inconvenience during infancy; as she grew up she occasionally suffered from palpitations and dyspnoea, and at the age of twelve she is represented to have enjoyed as good health as other people. M. Deschamp's case affords a still more remarkable example of the absence of any distressing symptoms from the displacement, though the heart was situated in the place of the left kidney. In this case the great vessels were disposed in the most favourable manner for transmitting the blood from the heart; but when the displacement is caused by accident or disease, the large vessels are necessarily contorted more or

less, in order to accommodate themselves to the new position of the heart; and if to this we add the pressure and consequent obstruction to the due discharge of their functions which the parts that the heart is forced amongst necessarily sustain, we shall see sufficient reason for concluding that the consequences must be most serious and detrimental when the displacement is at all considerable; but even to those untoward circumstances the powers of nature are capable of adapting themselves. In Dr. Stokes's case the patient, though occasionally subject to palpitations in the *right side*, has so much improved in health as to spend his time between shooting and fox-hunting. In all cases of displacement that we have seen the pulse was rapid and feeble, and the patient suffered from occasional attacks of dyspnoea and palpitation; but in each of these cases the displacement was complicated with empyema or pneumothorax, either of which was of itself sufficient to produce these symptoms. In general, however, we observed that they were immediately relieved by drawing off the fluid, and allowing the heart to resume its natural position. We are, therefore, disposed to conclude that slight displacements occasion little inconvenience, but when considerable they may produce serious functional derangements, especially until such time as the system has become habituated to the change.

The treatment of displacement of the heart must obviously depend on its cause; where that is of such a nature as to admit of removal, no sooner is its pressure taken off than the heart resumes its natural position, unless retained by morbid adhesions. When, on the other hand, the cause of the displacement does not admit of removal, the replacement of the heart is impracticable; and all that the resources of our art can effect is to palliate symptoms as they arise. In all our attempts, therefore, either to restore the heart to its natural position, or to mitigate the symptoms which its displacement produces, we should ever bear in mind that we are only treating a symptom—a mere mechanical effect of pressure; and that, by relieving the primary disease which caused the pressure, we take the most effectual method of remedying the displacement it produces.

On referring to the list of diseases we have enumerated among the causes of displacement, it will appear that many of them, such as aneurisms of the aorta, tumours developed within the thorax, &c. are of such a nature as not to admit of removal or diminution. Congenital malposition is equally irremediable: even in those cases where the heart was placed in front of the chest, immediately under the integuments, it was found that the attempt to force it into the thorax through the fissure in the sternum immediately brought on the most alarming symptoms.* In all such cases our best resource lies in the palliative treatment. The patient should be kept as quiet as possible, and every other precaution adopted to prevent

* Breschet, Mém. cit.

the circulation being excited. When palpitations are troublesome, digitalis may be administered with advantage; its exhibition, however, requires considerable attention, as it has been observed not to produce its effects in such cases unless administered in full doses, and we have witnessed the most alarming consequences from its over-action. Counter-irritation may likewise be employed with advantage; we have repeatedly found blisters applied over the heart most efficacious in controuling this symptom: when a more permanent effect is desirable, a seton may be introduced in the side near the heart. Dr. Stokes's patient, when we last saw him, declared that he experienced the most decided relief after the introduction of a seton into his right side, and that on one occasion when he withdrew it for a fortnight he was attacked with his former symptoms of pain and palpitation, which again disappeared after the seton had been introduced.

We have already stated our opinion that effusions into the pleura are decidedly the most frequent cause of displacement of the heart. By the operation of paracentesis thoracis these may no doubt be removed; but in deciding on the expediency of this operation there are many circumstances of greater importance than the displacement, which the physician must take into consideration. (See EMPYEMA.)

In the case of diaphragmatic hernia, Laennec suggests the idea of making an incision into the abdomen and drawing back the intestines. We conceive that if such an operation could ever be justifiable, it would only be when the pressure of the abdominal viscera on the lungs threatened immediate suffocation, in which case a doubtful remedy might perhaps be preferred to none: but how are the intestines to be prevented from again returning into the chest through the aperture in the diaphragm?

(R. Townsend.)

HEART, FATTY AND GREASY DEGENERATIONS OF.—In individuals of great obesity, and occasionally in others of only moderate *embonpoint*, the heart is sometimes overloaded with fat. It is deposited beneath the pericardium, and not only invests the organ externally, but frequently penetrates a considerable depth between the muscular fibres, which, as if losing (probably by the pressure) what the adipose tissue gains, become attenuated and flabby. Sometimes, however, the intermixture of adipose matter gives the appearance of attenuation, though there is none in reality.

The older authors imagined that this affection was the cause of more or less severe symptoms, and even of sudden death. Corvisart thinks that an enormous accumulation might sometimes be capable of producing such an effect; but, in the persons in whom he had met with very fat hearts, he had seen nothing which could prove to him "that the state was morbid, that is to say, carried to such a point as con-

stantly to derange the function of the organ and thus constitute a malady." The experience of Laennec has led him to the same conclusions; nor have we seen any thing that militates against them.

It would be natural to suppose that the substitution of adipose for muscular tissue, and the extreme attenuation which the walls, especially the apex and the posterior part of the right ventricle, sometimes undergo from this cause, would be eminently favourable to rupture of the organ; yet this accident is very rarely the result. Morgagni has seen an instance of it, but Bertin has only met with one of rupture of the auricle; while Corvisart and Laennec have not witnessed an instance at all.

Fatty degeneration is different from that denominated *greasy* degeneration of the heart. This, according to Laennec, is "an infiltration of the muscular substance with a matter which presents all the physical and chemical properties of grease;" it is an alteration exactly similar to the greasy degeneration which Haller and Vicq-d'Azyr have observed in the muscles. Laennec has never found it but in a very small portion of the heart, and only near the point. It was of a pale yellowish colour, like dead leaves, and therefore very similar to certain varieties of softening; but he thinks that it may be distinguished from softening by its strongly greasing paper between which it is pressed. We have seen a remarkable case in which a degeneration of this kind occupied the greater part of both ventricles.

(J. Hope.)

HECTIC FEVER.—See FEVER.

HEMATEMESIS.—This term (derived from *αἷμα* and *ἐμῆναι*) literally imports vomiting of blood, and is therefore properly employed to signify hemorrhage from the stomach. Some nosologists, as Pinel and Mason Good, comprise under this denomination every hemorrhage from the alimentary canal, whether the blood is discharged by the mouth or by the rectum. It is, however, more conformable to etymology and to general usage to restrict the name of hematemesis to *gastric* hemorrhage, and to denote *intestinal* hemorrhage by the name of *MELÆNA*, which will therefore be the subject of a separate article. There is, however, much affinity between these two species of hemorrhage; and the two articles will therefore be in some measure mutually supplementary.

Hematemesis is frequently mentioned by Hippocrates. It is clearly described by Aretæus, and distinguished by him from pulmonary hemorrhage. Among the moderns, Stahl, Hoffmann, Morgagni, Tissot, Portal, and subsequent writers, have contributed to its elucidation. Little has been written on the subject by British physicians. Cullen has not even included this disease in his nosological arrangement, on the ground of its being almost universally a symptomatic affection: he has, however, treated of it at some length in his

"First Lines," chiefly with reference to the diagnosis and pathology.

Predisposing causes.—Women are much more subject than men to hematemesis, and are chiefly liable to it during the menstruating period of their lives. Those of a delicate frame, of quick nervous sensibility, or subject to strong emotions, are most prone to this disease; but the sanguine, ruddy, and plethoric are also liable to it as a consequence of defective menstruation. In some females it occurs during pregnancy. Men are seldom attacked by hematemesis at an earlier age than thirty or thirty-five, and very rarely after fifty. It is in them almost invariably induced by habits of life unfavourable to health, especially by close and anxious application to business, combined with indulgence in the pleasures of the table, and neglect of bodily exercise. Organic disease of the stomach, liver, or spleen, and probably also of the pancreas, will constitute a predisposition to hematemesis; and organic affections of the heart, especially valvular disease and dilatation, by retarding the return of the blood, and hence inducing general venous congestion, are a frequent predisposing cause of this as well as of other hemorrhages. When hematemesis has once occurred in an individual, from whatever cause, a predisposition is induced to its recurrence, either spontaneously, or on exposure to some exciting cause which would not in other circumstances have given rise to it.

Exciting causes.—These may be divided into local and constitutional. The *local* causes are such as produce irritation or sanguineous congestion in the mucous membrane of the stomach, and consequent exhalation of blood; or more rarely a physical lesion of the inner surface of that organ, attended with rupture or erosion of a bloodvessel. Sauvages, Frank, and other authors, enumerate a variety of exciting causes of hematemesis, which are confessedly of very rare occurrence, such as the rupture of an aneurism of the aorta, or of some one of its branches, into the cavity of the stomach; the bite of a leech accidentally swallowed; wounds or irritation of the stomach from swallowing a bone, needles, broken glass, &c.; larvæ of insects introduced into the stomach, or generated there; the transmission of an electric shock through the region of the stomach.* Corrosive poisons are well known to induce vomiting of blood. Other acrid substances will probably have the same effect; and thus drastic purgatives and emetics are included in Frank's list of causes, but perhaps only from theoretical considerations. The effort of vomiting, and other violent strains and exertions, as the expulsive efforts in parturition, (*Frank*), are supposed to have produced hematemesis. It is also a well-known effect of severe blows on the epigastric region.

The *constitutional* causes are those which, by

some effect, not always easy of explanation, on the sanguiferous system, produce congestion in the vessels of the mucous membrane of the stomach, or a tendency in the blood to escape from them. Violent and especially *strongly concentrated* mental emotions, as grief, anger, or terror, are undoubted exciting causes of hematemesis, though probably only in the predisposed. In some malignant fevers, in scurvy, and in purpura, hematemesis occurs as a symptom, evidently from a constitutional cause. But the most frequent instance of such a cause operating in the induction of hematemesis, is, where it results from the suppression of some natural or habitual evacuation, especially of the catamenia in females, and of the hemorrhoidal discharge in either sex. The connexion of hematemesis with amenorrhœa has been remarked ever since the time of Hippocrates; and there appears to be no just ground for the denial of this connexion by Dr. Hamilton, in his work on Purgative Medicines. Hematemesis very commonly supervenes on a *suppression*, from whatever cause, of menstruation already established, and which had hitherto observed its regular periods. In other cases it is related to have attended upon *retention* of the menses,* but such instances are comparatively rare. (See AMENORRHEA.)

Symptoms.—The attack of hematemesis is sometimes unattended by any premonitory signs, the vomiting of blood being the first morbid symptom which occurs. But more frequently it is preceded by symptoms similar to those which precede ordinary vomiting; anxiety, faintness, a sense of weight and distention, sometimes amounting to dull pain in the epigastric region; and distressing nausea. The pulse is frequent, but commonly small and weak; and on inquiry it will be found that the bowels are costive.† Sometimes there is general chilliness, with particular coldness of the extremities, vertigo, impaired vision, and ringing in the ears; but several of these symptoms ought, perhaps, rather to be considered as indications that internal hemorrhage has actually taken place, than as precursory signs of its occurrence; for rejection of the effused blood by vomiting does not ensue, until either by its quantity or stimulus it excites the stomach and abdominal muscles to contraction.‡ The blood is then brought up with considerable violence in successive fluid gushes, or partly in solid coagula. Sometimes a single large coagulum is brought up, in fact a mould of the stomach. The quantity rejected by vomiting is always considerable, being seldom less than eight or ten ounces, and sometimes amounting to several pounds. It is highly probable that hemorrhage from the stomach may take place in smaller quantity; but then the blood passes off by the pylorus without giving rise to vomiting. The blood is of various shades of colour, from a deep red to nearly black, according to the shorter or longer

* *Sauvages*, Nosol. Method. *Frank*, de curand. homin. morbis, lib. v. part ii. p. 204. *Edin. Med. Journal*, vol. vii. p. 326. *Percival's Essays*, vol. ii. p. 183.

* *Frank*, op. cit. p. 206.

† *Chomel*, Dictionnaire de Médecine, tom. x. p. 555.

time that it has sojourned in the stomach, and probably from other causes. It is not to be supposed that when the blood is dark-coloured, it is necessarily the result of *venous* hemorrhage. This was pointed out by Aretæus; and it is well known that the fluid, and especially the gaseous contents of the stomach and intestines, will impart a dark colour to blood which remains for any time mixed with them. When there has been a sufficient delay for separation of the constituent parts of the blood to take place in the stomach, membranaceous or polypus-like concretions of fibrin are occasionally brought up along with the blood.* It is often mixed, as might be expected, with alimentary matters, with bile, or with the mucous secretions of the stomach. Most commonly blood is vomited only once in the course of a single accession of hemorrhage; but sometimes a repetition of the vomiting occurs after a short suspension. After the vomiting has subsided, the accompanying symptoms commonly cease, leaving the patient in an exhausted state, with a cold surface, pale countenance, and generally considerable mental agitation and alarm, especially in a first attack. Actual syncope, as Frank has noticed, not unfrequently ensues. Part of the effused blood usually passes the pylorus, and after a few hours produces slight tormina and distention in the course of the intestines, followed by two or three dark-coloured and offensive stools, resembling those in *melæna*. This appearance of the alvine discharge will continue for twenty-four or sometimes forty-eight hours.

Death has very rarely directly ensued from the loss of blood in an attack of hematemesis; but the repeated attacks of this hemorrhage have necessarily a tendency to weaken the constitution, particularly when it is not of a vicarious character. Sometimes after a single attack there will be no recurrence of hemorrhage; but more commonly, as we have already observed, a predisposition to its return is induced, and it will after some interval reappear, either spontaneously, or on the application of some exciting cause; or it will assume a periodical or chronic form, according to the nature of the local, constitutional, or organic cause by which it is kept up.

From the above account of the causes and symptoms of hematemesis, it will appear that it has generally the character of a *passive* hemorrhage. Sometimes, however, it occurs in individuals of vigorous constitution, is attended with symptoms indicative of increased impetus of the circulation, and puts on the type of *active* hemorrhage. This distinction is not always very clearly marked, but it is highly deserving of attention with a view to the treatment.

Hematemesis has also been divided into *idiopathic* and *symptomatic*; but these epithets have been used by different writers in widely different senses. The most important practical distinction is that derived from the several predisposing and exciting causes, and states

of the constitution, which give rise to the hemorrhage. These it is always highly important to ascertain.

Pathology.—As the general doctrine of hemorrhagic diseases will be developed in another place, (see *HEMORRHAGE*), we shall confine our present inquiry to those circumstances which are peculiar to this individual disease.

Hematemesis, when unconnected with organic lesions, so very rarely proves fatal, that anatomical investigation has thrown but little light on the state of the stomach and its mucous membrane in this disease. Frequently no morbid appearance whatever can be detected in patients who have died very shortly after profuse hematemesis. In other cases, *redness* of the mucous membrane could alone be discovered; but this may be the effect of simple infiltration of blood, while in other cases it may denote a congestive, or even an inflammatory state of the mucous membrane, which has caused the hematemesis. In some of the dissections recorded by Morgagni and Portal, the stomach and other viscera, after profuse hematemesis, were found remarkably pale. Some observers have recorded a dilatation of the venous and arterial branches supplying the stomach as a common appearance after death from hematemesis, and the veins ramified on the internal surface of that organ have been even described as in a varicose state; but these allegations are destitute of adequate proof.

In those cases of hematemesis which are connected with organic affections, whether of the circulating system or of the abdominal viscera, the appearances proper to these diseases will of course be met with after death. Where the hematemesis has arisen from organic disease of the stomach itself, it has commonly been supposed that it was the consequence of ulceration, producing the rupture or erosion of one or more bloodvessels. Such cases, no doubt, are occasionally met with; but it is no less certain that scirrhus of the pylorus often proceeds to extensive ulceration without the occurrence of any hematemesis; and on the other hand, as Andral from ample experience assures us, that scirrhus affections of the stomach are attended with repeated hematemesis during their progress, where, on dissection, no ulceration nor lesion of continuity in the mucous membrane or its vessels is observable.*

Hematemesis is, then, an instance of *exhalation* of blood from a mucous surface, analogous to what happens in epistaxis and hematuria, in uterine and many cases of pulmonary and bronchial hemorrhage. The causes which occasion this exhalation are referred by Andral to four heads:—1. a mechanical obstacle to the return of the venous blood through the system of the vena portæ;—2. irritation of the mucous membrane of the stomach;—3. sanguineous congestion, not referable to either of the former heads;—and, 4. certain states of the blood itself, in which it is so changed as to

* Frank, op. cit. p. 202. Dict. de Méd. loc. cit.

* Andral, Pathol. Anat. trans. vol. ii. p. 179.

have a universal tendency to escape from its vessels.*

Mechanical congestion is instanced (1.) in those cases of hematemesis which depend on enlargement or induration of the *liver*, and sometimes also of the *spleen* or *pancreas*, in consequence of which the trunk or branches of the *venæ portæ* are more or less directly compressed, and the return of the blood from the stomach impeded: hence congestion in its vessels and hematemesis ensue. (2.) In cases depending on obstructed circulation from organic disease of the *heart*, and more especially from morbid alterations in its valves, or dilatation of its cavities, in consequence of which the return of the blood by the *vena cava* is impeded, and general venous plethora is induced.† Such a state is now well ascertained to be a frequent cause of hemorrhage, especially from the lungs, the stomach, and the uterus; and its existence is a circumstance deserving of the most careful attention of the scientific practitioner.

Irritation of the mucous membrane is the direct cause of the hematemesis arising from corrosive poisons and other acrid substances.

To *simple congestion* we must, in the present state of our knowledge, refer all those cases of hematemesis which are considered as *idiopathic*, including those which are *vicarious* or *auxiliary* of suppressed or diminished menstruation, &c. "The blood," says Andral, "accumulates in some part of the mucous membrane, and escapes from its vessels, which is all that we can discover."

The subject of *morbid changes of the blood* will be discussed in other parts of this work. (See BLOOD, PURPURA, SCURVY.) Andral instances, as cases where hematemesis results from this cause, "certain cases of poisoning by absorption," typhous fevers, and the black vomit in yellow fever.

Diagnosis.—Hematemesis is in general easy to be recognized by the symptoms already enumerated. It is occasionally liable to be confounded with hemoptysis. "It may be certainly known," says Cullen, "that the blood proceeds from the stomach, and not from the lungs, when it is manifestly brought up by vomiting, and not by coughing; when the vomiting has been preceded by some sense of weight, anxiety, and pain in the region of the stomach; when the blood brought up is of a dark and grumous appearance; and when it is manifestly mixed with the contents of the stomach."‡

When, also, cough and the other local and constitutional symptoms of pulmonary hemorrhage are absent, we may in general safely conclude the case to be hematemesis. There are, however, several circumstances which may tend to perplex the diagnosis. Cough and vomiting will materially excite each other; and when they jointly occur, it may not be easy to decide which is the primary symptom,

and by means of which of them the blood is brought up. In very profuse hemoptysis the muscles of the thorax will sometimes contract convulsively, so as to send forth the blood in successive gushes, closely resembling what takes place in true vomiting of blood; or the blood brought up by coughing may tickle the fauces, and excite actual vomiting. On the other hand, blood brought up by vomiting may be driven back into the glottis, and excite violent cough. We must also recollect, in order to guard against all error in diagnosis, that the blood, though actually vomited up from the stomach, may be originally derived from a different quarter, as in the case of aneurism already adverted to, or where blood proceeding from the fauces or posterior nostrils has been swallowed during sleep, or is transmitted from a vomica in the lung by a fistulous canal into the œsophagus, as in a remarkable case related by Dr. Mackintosh.*

Hemorrhage from the stomach, as has been already mentioned, does not necessarily imply the rejection of the blood by vomiting; for in the first place the quantity of blood exhaled into the cavity of the stomach may be so inconsiderable as not to excite vomiting, and pass off by the intestines; and, secondly, in very debilitated states of the constitution, the relative loss of blood may be such as instantly to destroy life, before any vomiting has taken place. This chiefly occurs in cases of ulceration of the stomach, which organ is found after death distended by an enormous coagulum. Such cases are not of very rare occurrence.

The diagnosis of hematemesis is not complete for practical purposes until we have endeavoured to ascertain to what specific cause the hemorrhage is to be ascribed, and whether it be idiopathic or symptomatic, connected with organic lesion or simply with deranged function, and whether it partakes of the character of *passive* or *active* hemorrhage. Attention is therefore required to what has been pointed out on these several heads.

Prognosis.—Hematemesis is always a disease of formidable and alarming appearance, from the quantity of blood which is lost, and the delicacy and importance of the organ concerned. Experience, however, instructs us that in many cases it is attended with little danger. Hematemesis which is vicarious or supplementary to menstruation is usually a very manageable complaint; though we cannot go so far as some of the older authors, who considered it as absolutely salutary, and not to be interfered with.‡ Where, on the other hand, it is not imputable to suppressed evacuations; where it shows a tendency to assume a chronic form; where it is attended with fever or indications of organic lesion; hematemesis is a disease of considerable danger, and very difficult of cure.

Treatment.—The treatment of hematemesis

* Pathol. Anat. transl. vol. ii. p. 179.

divides itself into three heads:—1. prophylactic measures; 2. those proper at the time of an attack; 3. those suitable in the intervals, or after the hemorrhage has subsided.

1. When warning is given of the approach of an attack of hematemesis by any of the precursory symptoms already noticed, it will be proper to have recourse to timely preventive measures, and especially to prescribe rest and the antiphlogistic regimen, cooling drinks, warm pediluvia or fomentations to the extremities, saline or other purgatives, and, if indicated, the abstraction of blood. Small bleedings have been particularly recommended a day or two before the time at which the catamenia ought to recur, if it is apprehended that they will be replaced by hematemesis.

2. The attack of hematemesis must be met by remedial measures of the same kind as those which are suited to hemorrhagic diseases in general; and their use must be modified by the character of the hemorrhage, the symptoms by which it is accompanied, and the causes which appear to be concerned in its production.

If there are clear indications that the hemorrhage is of an *active* or inflammatory character, venesection must be promptly resorted to, and followed up by purgatives and a strict antiphlogistic regimen. If, on the contrary, the disease puts on a *passive* or asthenic character, and the constitutional powers evince a tendency to sink rapidly, we must have early recourse to the most efficacious astringent remedies, and support the strength by mild but invigorating nourishment, and even cordials, given in small quantities, but frequently. In cases of an intermediate nature, the judicious combination and modification of these two plans of treatment demands the discrimination and skill of the practitioner. Thus it may be necessary to reduce local action by leeches, cupping, and mild laxatives, while proper dietetic means are resorted to to support the strength.

In all cases the most perfect mental and bodily tranquillity must be enjoined, and the patient strictly confined to the horizontal posture, in a cool and well-ventilated apartment, and with as light coverings as possible. Castor-oil, the neutral salts, or more active purgatives, are to be administered according to circumstances; or where the irritability of the stomach forbids their use, laxative clysters must be resorted to, to secure an open state of the bowels. Cold liquids, as lemonade, almond emulsion with nitre, or the super-acidulated infusion of roses, may be given frequently in small quantities, as a tea-spoonful or dessert-spoonful at a time.

In cases where the hemorrhage is so profuse and violent as to threaten serious consequences, more active measures must be resorted to; and none is so deserving of confidence as the free application of *cold*, which is the most efficacious of all astringents, by diminishing the calibre of the bloodvessels and lessening the impetus of the circulation. We must, therefore, not only give the liquids just mentioned, cooled down to 32° by ice or a freezing mixture, but may with great advantage inject

iced water into the rectum, and lay bladders filled with pounded ice on the epigastric region. A very interesting case is related by Michelotti, in the *Philosophical Transactions* for 1731, in which a young gentleman affected with enlarged spleen, and previously subject to epistaxis, was cured of a second attack of profuse hematemesis, in the winter season, by drinking excessively cold water, and taking alimentary liquids iced. The quantity of blood vomited in the space of two hours is said in this case to have amounted to twelve pounds and upwards. By means of occasional small bleedings, a fresh attack was averted for two years, at the end of which period the hemorrhage recurred, and was again subdued by the same means. In the remarks appended to this case, the author cautions us against resorting to this powerful remedy in asthenic or dyspeptic individuals, but strongly advises its use in young and vigorous constitutions, and in the active form of hemorrhage.*

It is, on the contrary, in the *passive* kind, and in relaxed and languid subjects, or where the impetus of the circulation has been already reduced by venesection and antiphlogistic measures, that the vegetable and mineral astringents may with safety and advantage be employed. In hematemesis we have the great advantage of applying these remedies directly to the seat of the hemorrhage; and, therefore, they may be the more relied upon. Preparations containing gallic acid, such as Ruspini's styptic, (which Dr. A. T. Thomson has ascertained to be a solution of this acid in diluted alcohol,) are probably the most useful of the vegetable astringents. But no remedy of this class deserves so much confidence in passive hemorrhage as the acetate of lead given in combination with opium, and in such large doses and at such frequent intervals as to secure its effect. (See *ASTRINGENTS*.) Dr. Elliotson, who strongly advocates the *free* employment of this remedy, also mentions, as one from which he has derived great benefit in hematemesis and melæna, the oil of turpentine, in doses of twenty drops, repeated every three hours.† Subnitrate of bismuth, in conjunction with opium, has also been recommended.

3. After the hemorrhage has subsided, or in the intervals of its occurrence, we must endeavour to obviate its return by removing or weakening the exciting causes, and counteracting the predisposition to the disease. A strict regulation of the diet, (passing very gradually from the mildest liquids to more nutritious food,) rest, quietness, the horizontal posture, cooling and astringent beverages, will be proper for several days after the hemorrhage has ceased. The bowels must be kept properly open by the gentlest and at the same time most effectual means; and there can be no

* *Philosophical Transactions*, vol. xxxvii. p. 129. —Ploucquet refers to two cases cured "gelidissimo potu."—1. *Act. Nat. Curios.* vol. iii. obs. 61; 2. *Comm. Liter. Noric.* 1732, pp. 294, 351, 381. † Elliotson's *Lectures*, *Medical Gazette*, vol. ix. p. 525.

doubt that the recommendation of clysters, to clear the intestines of the blood lodged in their course, so much insisted upon by continental physicians, is a judicious and salutary practice. We cannot, however, in this country, go along with them in their unanimous and strong condemnation of *purgatives* in every case of hematemesis, at least of such as are more active than manna, cassia, and tamarinds. "Quæ vi alvum movendi majore instructa sunt, ea," says Frank, "cane pejus et angue vitanda sunt."* And other continental writers, from Hoffmann down to Pinel, are not less explicit in their reprobation of active, and especially aloetic purgatives.† British practitioners, especially since the publication of Dr. Hamilton's treatise,‡ have placed great confidence in active purging as the best mode of treatment in many cases of hematemesis, more particularly in that form of the disease which occurs in young and middle-aged females, and is connected with uterine torpor and a sluggish action of the bowels. In such cases Dr. Bateman states, as the result of his experience, that the success of Dr. Hamilton's mode of treatment is more decidedly conspicuous than in any other disease in which he has recommended it.|| It is remarkable that the benefit of the purgative plan of treatment is not confined to sanguine and plethoric subjects; it is not less signal in chlorotic and leucophlegmatic habits. It is, however, to female cases exclusively that the observations of Hamilton and Bateman apply; and there can be no doubt that the inconsiderate employment of active purgatives in cases of hematemesis or melæna occurring from wholly different causes, especially in constitutions exhausted by excess, or debilitated by the progress of organic disease, would be highly pernicious. In such cases certainly the more cautious procedure of our continental brethren is to be commended.

With regard to the restoration of the menstrual function where its suspension gives rise to hematemesis, the means by which this is to be accomplished are rather such as act by removing a condition of the general system unfavourable to regular menstruation, than by the employment of specific emmenagogues. If, therefore, the amenorrhœa depend on vascular fullness, we resort to bleeding and suitable purgatives; if on uterine torpor and a chlorotic state, the warmer aperients and tonics, especially the preparations of iron, are to be employed. (See AMENORRHŒA, CHLOROSIS, and EMMENAGOGUES.)

To complete the recovery of the convalescent from the various forms of hematemesis, tonic medicines, a suitable diet, exercise, change of air, and sometimes the use of chalybeate mineral waters, will be highly serviceable. But it is not necessary to protract this article by dwelling on these familiar topics. Freedom

from care, anxiety, and causes of mental irritation, is of the highest importance in all cases, and especially where we have reason to believe or suspect the existence of organic disease. In such melancholy cases the utmost that our art can aim at is to palliate suffering, to ward off the recurrence of hemorrhage, and to protract to the utmost that fatal event which the resources of medicine, however skilfully wielded, cannot hope to avert.

(George Goldie.)

HEMICRANIA.—See HEADACH.

HEMIPLEGIA.—See PARALYSIS.

HEMOPTYSIS, from αἷμα, *blood*, and πύσις, *spitting*.—Were it taken in the full latitude of its etymology, the word hemoptysis would embrace every discharge of blood from the mouth, without regard to the sources from whence it originally proceeds; but as the sources are various, use has annexed to the term a more limited signification, restricting it to *expectoration of blood*, or that which originally issues from the respiratory organs. This view of the subject has suggested to some the propriety of substituting the term *pneumorrhagia*, as more definite and precise in its signification. We, however, do not recognize, in the proposed substitution, advantages sufficient to counterbalance the evil of disturbing a well established name. Were we disposed to make any change, it would be to divide the subject into pulmonary hemorrhage and hemoptysis; the former expressive of the more profuse discharges of blood, the latter of the smaller quantities discharged as sputa. Still we prefer the general term hemoptysis taken in its conventional signification.

If there be no subject within the extended field of pathology upon whose precise nature the advancement of anatomical knowledge has thrown more light than hemorrhage, there is unquestionably no organ in the body that has derived more benefit from this circumstance than the organs subservient to respiration, which, both from their organization and from the nature of their functions, are more frequently than any other the subject of hemorrhage.

The term *hemorrhage*, (αἱμορραγία, from αἷμα, *blood*, and ῥήννμι, *to break*,) carries upon its face evidence of the imperfect views which prevailed respecting the real nature of this morbid phenomenon, implying rupture of a vessel to be its essential cause; but experience, so far from establishing this as a general cause, has proved it to be of very rare occurrence, even under circumstances which we should have supposed most likely to produce such a lesion. This pathological error has been kept up in the application of the expression "bursting a blood-vessel." Speculation and vague hypothesis filled up the imperfect measure of information upon this important pathological subject, until the invaluable labours of Bichat redeemed it from error, and placed it in its true light. In explaining the phenomenon of exhalation, he

‡ Observations on Purgative Medicines, Edinburgh, 1805.

|| Reports on the Diseases of London, p. 150.

has shown that it is effected through the instrumentality of a system of vessels which are continuous with the arteries, namely, the *capillaries*; that these vessels enter into the composition of all our organs; that they become elements of the several tissues of the body; and that their function consists in separating from the blood a fluid peculiar to the tissue of which they form part. Thus the mucous exhalants separate mucus, and the serous serum; and as long as these vessels continue in the unimpaired enjoyment of their vital properties, so long they only admit the colourless fluids, and refuse entrance to the red particles of the blood; but should these properties be so affected, either directly or sympathetically, that they are either altered or impaired, (changes to which they are especially subject from their being more under the influence of the nervous system than any other portion of the vascular apparatus,) they no longer retain this power of closing themselves against the entrance of red blood. In one case they as it were solicit the presence of this fluid, and in another yield to its forced entrance; in the former instance giving rise to *active*, in the latter to *passive* hemorrhage. Between the first of these morbid conditions and inflammation the closest analogy exists: they recognize the same causes; occur most frequently in the same tissues; have often the same symptoms and terminations; and not unfrequently pass into each other.

These considerations lead to the conclusion that the disposition of an organ to hemorrhage is in a ratio compounded of the development of the exhalant vessels in that organ, and of their exposure to the operation of causes capable of producing those changes in their properties upon which hemorrhage, whether active or passive, is found to depend. Applying this to the lungs, we have a ready and satisfactory explanation of the frequency of pulmonary hemorrhage. These organs combine in themselves every condition favourable to the production of this morbid phenomenon, both in its active and passive form: 1. a considerable extent of mucous membrane, the tissue the most richly furnished with exhalant vessels of any in the animal economy; 2. the constant and immediate relation of this tissue with the atmosphere,—a source of irritation not only from the variations of temperature of which it is so susceptible, but also from the different impregnations with which it is continually charged; 3. a loose spongy parenchyma traversed by numerous bloodvessels of every dimension, freely communicating with each other; 4. the proximity of these organs to the heart, and consequent exposure to the effects of every irregular motion of this organ; 5. the continued motion which the exercise of their own functions entails upon them.

In order to appreciate the disposition of the lungs to hemorrhage still further, we shall briefly glance at the two systems of bloodvessels which traverse them, viz. the bronchial or proper nutrient vessels of the organs, and the pulmonary vessels, whose office consists in

the transmission of the blood through the lungs, for the purpose of its undergoing the proper chemical changes to fit it for its several uses.

The bronchial arteries are distributed to all parts of the lungs. Their trunks follow the course of the bronchi, and, sending off twigs to all the branches given off from the bronchial tube, accompany them to their ultimate termination. These numerous bloodvessels, after embracing the bronchi, penetrate their coats, and are spread out upon their mucous surface into an incredible multitude of capillaries. In addition to these branches supplying the bronchi, the bronchial arteries send lateral branches to all other parts of the lungs, which, passing into the tissue of the organ in connexion with numerous branches of the pulmonary artery and pulmonary vein, constitute a fine network made up of innumerable capillaries freely anastomosing with each other.

The pulmonary artery, after it has pursued the bronchi to their termination, sends branches to each vesicle; and these branches, anastomosing on all sides, are spread out upon the vesicles. This artery gives off vessels which, pursuing a tortuous course between the air-cells, proceed to take their share in the composition of that network of vessels to which we have before adverted as made up of the ultimate ramifications of the bronchial and pulmonary arteries and pulmonary vein. Through the medium of these vessels, an injection thrown into the bronchial artery fills the pulmonary artery also, though its passage from the latter into the former is much more easy.

The pulmonary veins, made up of branches collected from all points to which the bronchial and pulmonary arteries carry the blood, conduct this fluid back to the heart, pursuing their course along the bronchi and their branches in the same way as the pulmonary artery.

These anatomical details explain to us, so to speak, the machinery of pulmonary hemorrhage, and enable us to understand the mode of operation of the many and different causes which produce this morbid phenomenon. They exhibit to us such a freedom of communication existing between all the bloodvessels of the lungs, that any derangement of either the general or pulmonic circulation is competent to give rise to it. In certain excitements of the general circulation, the blood will be impelled through the bronchial artery, proceeding from the aorta, into the smaller vessels which are spread upon the bronchial mucous surface, and from them into the bronchial tubes. Should the derangement be more particularly confined to the pulmonary circulation, as in case of hypertrophy of the right ventricle of the heart, the blood will then be driven into the small branches of the pulmonary artery which are distributed to the parenchyma of the lung, and, being exhausted there, will constitute hemorrhagic engorgement or pulmonary apoplexy; and, should the impetus be considerable, its effects will be extended to the communicating bronchial branches, from whence the blood will be poured into the bronchial

tubes, giving rise to bronchial hemorrhage. See APOPLEXY PULMONARY.

We are now prepared to understand a circumstance to which we shall have occasion to advert when we come to speak more particularly on the subject of pulmonary apoplexy. Although this affection generally consists in the extravasation of blood into the parenchyma of the organ, and of hemoptysis more or less extensive at the same time; still this latter phenomenon may be altogether absent, and the hemorrhagic engorgement (which is really the essence of the disease) alone be present. In fact, we regard the addition of the hemoptysis as a mere accident, though a measure of the intensity of the cause which has given rise to the hemorrhagic engorgement; and we readily account for its frequency by the facility with which an injection is found to pass from the pulmonary into the bronchial artery. The communication which we observed to exist between the pulmonary vein and pulmonary and bronchial arteries, furnishes us with the *rationale* of hemoptysis dependent upon particular lesions affecting the left side of the heart. Thus, from a narrowing of the communication between the left auricle and ventricle, the pulmonary vein is *prevented* emptying its blood into the auricle; and as it is the channel into which the pulmonary and bronchial arteries empty their contents, the effects of its congestion are necessarily felt in these arteries. Besides, the remora of the blood in the lungs opposes a resistance to the efforts of the right ventricle to drive its blood through the pulmonary artery and lungs, and, demanding increased efforts of this ventricle, occasions its contents to be thrown with unusual force into the minuter vessels of the pulmonary artery, and the communicating minute branches of the bronchial artery: it is in this way that we explain the frequent hemoptysis in this particular lesion of the heart. From the foregoing observations it is obvious that the bloodvessels of the lungs form a circle; and that hemoptysis may result from derangement of the circulation affecting any part of it.

Though there is no period of life which can be strictly said to be exempt from hemoptysis, still it is so much more frequent from the age of fifteen to thirty-five, that this has been considered its proper season. This is the period when the energies of the system seem to converge towards the organs of respiration; and when are developed between them and distant organs those sympathies upon which their susceptibility to certain diseases would seem to depend. This is the period when phthisis strikes its victim; and when we come to speak more in detail of the particular lesions of the lungs which give rise to hemoptysis, we shall see how often it occurs as a symptom of this disease.

Hemoptysis sometimes comes on quite suddenly, and without any premonitory announcement. It is, however, in general preceded by chilliness of the skin, lassitude, alternating paleness and flushing of the face, head-ach, palpitation of the heart, and strong

vibrating pulse. To these may be added what we may term the local symptoms, consisting of a painful sensation of weight and tension, and of heat and itching in all or in some part of the chest, with dyspnoea, and a sense of anxiety about the *præcordia*: these symptoms are due to the congestion which immediately precedes the effusion of blood. Other symptoms are enumerated, which are in reality owing to the blood already effused into the parenchyma of the organ, and into the bronchial tubes. Among these the most remarkable are a sense of ebullition in the chest, (a feeling produced by the mixture of blood and air from the successive movements of inspiration and expiration,) and a great increase of dyspnoea.

When blood is effused into the air-passages, the irritation it produces causes cough, which determines its expulsion; and when the effusion is considerable, (which it is sometimes, to the degree of producing an urgent sense of suffocation,) the muscles of expiration contract almost convulsively, the lungs are compressed, and the blood is expelled with violence through the mouth and nose. Sometimes some of it, passing into the stomach, excites vomiting and is rejected with the contents of this organ; a circumstance which may embarrass our diagnosis as to the original source of the hemorrhage.

Hemoptysis varies considerably in the quantity of blood discharged. Its extent is sometimes so great that we wonder how it can take place, and not extinguish life; still we see the same quantity discharged again and again at intervals not very long distant, and this go on for months, nay for years, and the subject of it ultimately restored to the enjoyment of perfect health. At other times, we regard with alarm even the appearance of expectorated blood, when we have reason to look upon it as the index of deeper mischief latent; a single sputum tinged with blood will then bespeak more danger than a loss, frightful in quantity, under different circumstances. From this we may conclude that the extent of the hemoptysis is not in all cases an exact measure of the amount of danger; and that in general its importance is derived from the circumstances under which it takes place.

We should be acquainted with the appearances presented by expectorated blood, as a circumstance to guide our diagnosis. When it is not in considerable quantity, it is generally frothy or mixed with air, and of a vermilion or arterial colour; if it be considerable, it is not frothy, but has the arterial colour. These appearances, however, are not sufficiently constant to enable us to rest our judgment on them alone: we must have recourse to other signs and symptoms, both positive and negative, before we deliver our opinion in doubtful cases.

Among the constitutional symptoms of hemoptysis, some depend upon the actual loss of blood; others are due to the alarm or nervous shock produced by this phenomenon, which is so often associated with circumstances of

danger. In this way alone can we explain the exanguious appearance, the tremor, the hurry of the circulation, the irregular action of the heart, the fainting which we find so often to follow the loss of even a moderate quantity of expectorated blood. We constantly observe a loss of blood apparently trifling produce more disturbance in a nervous delicate person, than a very considerable loss will do in one of a strong vigorous constitution: in fact, fright and hemorrhage have precisely the same physiological operation, and give rise to the same phenomena.

Hemoptysis is the consequence either of congestion of the lungs, (whether caused by the blood thrown upon these organs with unusual force, or by its remora in them,) or of some lesion of those organs: we shall therefore consider it under these circumstances respectively.

When we reflect upon the organization of the lungs, we cannot wonder that they should often be the organ through which nature relieves herself from a state of morbid plethora; especially should that state depend upon the suppression of a hemorrhage which ordinarily takes place from an organ between which and the lungs a sympathy is known to exist. Physiology has ever recognized a remarkable sympathetic relation to exist between the organs of respiration and the uterine system; in virtue of which the lungs (especially when possessed of any particular susceptibility of disease whether natural or acquired) seldom remain long unaffected, should there be any interruption to the development or regularity of the functions of the uterus. This is the most fertile source of hemoptysis, independent of organic lesion of the lungs. In some of these cases we find the hemoptysis anticipating the period of the establishment of the menstrual discharge, and entirely ceasing when this discharge has been fully established. In other cases we find the hemoptysis altogether superseding this discharge, usurping its regular periodical appearance, and establishing itself into a function, so connected with the health of the system as to require much caution to be observed in interfering with it. Again,—and which is the most common case,—the hemoptysis is a supplementary discharge, making up for the deficiency of the menses: in these instances nature seems to make an effort to establish the due order of her functions; pains in the back and loins are felt at the same time as a sense of weight and tightness in the chest, with oppressed breathing; upon these follow a mere appearance of the menstrual discharge, and a more profuse discharge of blood from the chest. This state of things will sometimes continue till the period of life when the menses usually cease, with no more inconvenience than the occasional oppression caused by the congestion which precedes the hemoptysis. Hoffmann mentions a remarkable case in which the hemoptysis usurped the place of the menses: the subject of it became pregnant, the hemoptysis was then suspended, and reappeared after delivery, and continued for many years.

Suppression of the hemorrhoidal discharge will give rise to hemoptysis. Between this and the hemoptysis connected with suppressed menses, Laennec makes the distinction that the former occurs as pulmonary apoplexy, and the latter as bronchial hemorrhage. This hemorrhage exhibits the same tendency to return as the discharge which it has superseded. Masson (*Dissertation sur l'Hémoptysie*) records a remarkable case where the hemoptysis, which succeeded a suspended hemorrhoidal discharge, returned regularly every month for a year, although the original discharge had not observed the same periodical regularity.

Hemoptysis occurs sometimes, though rarely, as a critical discharge. Nature, in directing her critical efforts to other organs in preference to the lungs, would seem as if she respected these organs in consideration of their importance, and of the danger that might result from their being the subject of hemorrhagic congestion.

Any circumstance, which, by interrupting the balance of the circulation, throws an unusual quantity of blood upon the lungs, may act as a cause of hemoptysis. It is thus that the bent position of the body, which certain trades require, acts. Tailors are, for this reason, much subject to this affection: their constant sitting posture, with the body bent and head leaned forward, and with the abdominal viscera so compressed as to admit a less than natural quantity of blood into them, favours an unequal distribution of this fluid, which is directed in an undue proportion towards the lungs, and produces in them a local plethora, a frequent result of which is hemoptysis.

Malformation of the thorax, by compressing the lungs, and thus interfering with the free exercise of their functions, often causes hemoptysis; a fact already noticed by Morton.

Prolonged pressure upon the abdomen by tumours, whether solid, fluid, or gaseous, produces hemoptysis, by diminishing the quantity of blood sent to this region, and increasing that which is carried to the chest. In advanced pregnancy hemoptysis is sometimes so considerable as to demand instant delivery. Stoll mentions a case in which hemoptysis came on during ascites: it ceased on tapping, and reappeared on the fluid accumulating again. Tympanitis has been known to be attended with a similar result.

Hemoptysis is often caused by a paroxysm of some of the diseases classed under the head of *neuroses*. Bohn mentions a case of epilepsy, each attack of which brought on a profuse hemoptysis. We have often had occasion to observe the same in paroxysms of hysteria.

M. Fougnet, Professor at Montpellier, treated successfully with bark a tertian which was always ushered in by an hemoptysis so considerable that the patient seemed to vomit blood.

Low, asthenic fevers, accompanied with petechiæ, often exhibit this phenomenon. It was much more common in eruptive fevers before Sydenham improved the practice in this class of diseases. Haller observed, in an

epidemic small-pox, that all who were treated upon the cordial heating plan were covered with livid spots, the appearance of which was preceded by pains in the back and chest, and by hemoptysis. Diemerbroeck, in his description of the plague which ravaged Belgium and Germany in the middle of the seventeenth century, mentions the hemorrhagic flux from the nose, uterus, urinary passages, and lungs. Fracastorius makes the same observation respecting the plague of the fourteenth century.

Besides this accidental complication of fever and hemorrhage, authors admit a hemorrhagic fever, in which the fever is as essentially connected with the hemorrhage, as the fever preceding and accompanying small-pox is part of that disease. This fever may be either sthenic or asthenic in its type, and the accompanying hemorrhage either active or passive in its character. The most striking feature of sthenic hemorrhagic fever is the full, bounding, vibrating pulse, so characteristic of this morbid condition that by it alone we can almost predict an impending hemorrhage.

We have already anticipated our observations upon hemoptysis resulting from congestion of the lungs, the effect of disease of the heart, and explained its frequency in that particular lesion which consists in a narrowing of the communication between the left auricle and ventricle. The following case will illustrate this point. We had under our care, for three years, a young female who laboured under most distressing palpitation, greatly increased by the slightest exertion or motion: the phenomena of auscultation left no doubt that the lesion consisted in a narrowing of the left auriculo-ventricular opening of the heart. She had repeated hemoptysis, which became more frequent and profuse as she approached death. Examination of the body after death exhibited both lungs gorged with blood; even the minutest capillaries under the pleura were injected; and there were numerous ecchymosed patches in the cellular tissue subjacent to this membrane. The heart did not exceed the natural size; its right ventricle was both in a state of hypertrophy and dilatation; the left ventricle was smaller than natural; the capacity and muscular structure of the left auricle were unusually developed; the communication between the left auricle and ventricle would scarcely admit the introduction of a crow-quill. The pulmonary artery exceeded its natural size; the calibre of the aorta scarcely equalled that of the common carotid. This is the lesion which we shall find to be most frequently the cause of pulmonary apoplexy; a form of hemorrhage to which we shall have occasion to advert when we come to speak of the morbid conditions of the lungs which give rise to this phenomenon.

Hemoptysis arises no less from moral than from physical causes. Moral causes operate principally in the production of hemoptysis through the medium of the heart; in fact, the lungs and heart have such an intimate sympathetic relation, that one cannot be affected without involving the other; so that it is not always

easy to determine which has preceded in the order of their derangement. There is no organ in the body more subject to disturbance of its function from the irregular play of passion than the heart; and whether that passion be of the exciting or depressing character, it is equally capable of producing hemoptysis. These two orders of moral affections act upon the heart as stimulant and sedative agents do; the former throwing an unusual quantity of blood upon the lungs; the latter, by weakening the impelling power of the heart, giving rise to a stagnation of blood in them. In addition to hemoptysis proceeding from these palpable causes, we sometimes meet with it under circumstances in which we cannot fathom its etiology; when, perhaps, it depends upon some particular state of the capillaries, which our imperfect knowledge of this portion of the vascular system prevents our appreciating. One of these mysterious cases is that remarked by Dr. Cheyne in the fifth volume of the Dublin Hospital Reports: the subject of it has had, since 1807, frequent attacks of hemoptysis coming on at variable intervals, but nearer to each other in spring. We have had recent communication with this individual on the subject of his disease, and have been informed that it comes on without any provocation, and when at its height returns three or four times in the course of the day: it is not influenced either by rest or by exercise, and does not seem to yield to remedies, but subsides spontaneously. Previous to the attack a sense of constriction is felt in the chest; there is no fever, the pulse not exceeding eighty-four beats in the minute. A system of small bleedings from the arm, adopted at the suggestion of Dr. Cheyne, gave the first check to his disease, and by following it up he is now enabled to engage in the active duties of his profession as a clergyman, and feels no inconvenience from an unsparing exercise of his voice.

We now come to consider hemoptysis in connexion with actual lesion of the lungs.

Unquestionably the morbid condition of the lungs with which hemoptysis is most frequently associated, is the development of tubercles: this is a pathological fact universally admitted, though the question whether the hemoptysis, which so often ushers in phthisis pulmonalis, be the harbinger of tubercles, or the index of their actual existence in the lungs, is still *sub judice*, each opinion reckoning among its advocates the highest pathological authorities. Laennec is of opinion that the formation of tubercles precedes the hemoptysis, and that the contrary opinion is founded upon the hasty application of the axiom, *post hoc, ergo propter hoc*; that though the hemoptysis is the first symptom of the disease which attracts notice, still, if the chest be examined before its appearance, there will be evidence of the existence of tubercles; and as hemoptysis often recurs in the progress of the disease, we may conclude that the presence of tubercles is its most frequent occasional cause. He further adds that the mode of their operation

in the production of this effect is easily understood, when we consider that they are foreign bodies, which in their development press upon and irritate the parenchyma of the organ; that, on the other hand, we want a positive fact to prove that hemoptysis alone can produce tubercles; nor can we conceive, anatomically, how that can be the case; for if it were so, we should see hemorrhagic engorgement transformed into miliary tubercles, a circumstance which he had never observed. Besides, he observes, hemoptysis resulting from violence is nothing more than a mere accident, unattended by any unpleasant sequelæ if properly treated; whereas tubercular phthisis, long latent, often manifests itself immediately after an hemoptysis coming on without any appreciable cause, and which has no other cause than the presence of tubercles in the lungs.

Andral, in advocating the opinion of the hemoptysis preceding the formation of tubercles, and being their actual cause, says he has more difficulty in conceiving how tubercles, which, according to those who espouse the former opinion, have the power of irritating the pulmonary parenchyma to the degree of producing abundant hemoptysis, can exist for a long time without causing even a slight cough, than that under causes more or less appreciable some portions of the lungs should become the seat of sanguineous congestion, and give rise to hemoptysis. If this congestion exist in one or more points of the lung, and if at the same time the subject be predisposed to tubercles, these bodies may arise easily, and multiply rapidly, in the midst of a part whose nutrition is modified in consequence of the new state in which it is: it is thus that he would explain phthisical symptoms so often following hemoptysis, although well-directed treatment will often avert the mischief.

Louis thinks that hemoptysis, unless connected with irregular menstruation, or dependent upon external violence, furnishes strong presumptive evidence in favour of the existence of tubercles in the lungs; an opinion sustained by actual observation and the analogy of other organs, in which, when hemorrhage occurs, it is the index of some serious alteration in their structure: besides, it is natural to suppose that the same cause which produces hemoptysis in the progress of the disease, produced it also in the beginning.

We may infer that Broussais is of opinion that hemoptysis precedes the formation of tubercles, from his observation that the loss of blood is not to be considered the direct cause of consumption, but as one of the inflammatory movements which are the sole cause of phthisis.

Amidst these conflicting opinions, we hesitate to express a decided judgment, while we admit a bias in favour of that which considers the formation of tubercles to precede the hemoptysis. In the examination of those who have died of hemoptysis, we have found tubercles, the existence of which was not suspected during life; and we have ever regarded the mode of operation of tubercles in the lungs to

be precisely similar to that of foreign substances in other parts of the body, each tubercle or cluster of tubercles acting as a nucleus or centre of irritation, and soliciting to the part an unusual flow of blood.

In admitting the difficulty of deciding between these opposite opinions, it happens fortunately that the difference carries with it no practical inconvenience, as whichever view be adopted, it involves no difference of treatment. So frequent an accompaniment of phthisis is hemoptysis, that Louis found it to exist in two-thirds of the cases which fell under his care.

Andral observed, that among those that die of consumption, a sixth have never spit blood; three-sixths or a half never spit blood till pulmonary tubercles had given unequivocal evidence of their existence; and in the remaining two-sixths the hemoptysis seemed to precede and be the actual cause of the tubercles.

There are three principal sources from whence the blood expectorated in these cases may be derived; either from the mucous membrane of the bronchi, or from a tubercular cavity, or from the parenchyma of the lung. Death is sometimes caused by hemoptysis, when examination can detect no other source of it than the bronchial mucous membrane, which, in this case, only exhibits a slight blush, or is even paler than natural. As hemoptysis is found to be more frequent when tubercles are in their crude or nascent state, we may account for the repetition of this phenomenon by the successive development of these bodies through the course of the disease, on the physiological principle above noticed, *ubi stimulus, ibi fluxus*. We may perhaps ascribe the frequency of hemoptysis at this stage of the disease to the obstruction to the pulmonary circulation caused by the extensive tubercular development in the lungs; this obstruction demands an increased energy of the right ventricle, whereby the blood is thrown with unusual force into the lungs, and hemorrhage is thus produced. This we may expect to be most frequently the case when the tubercles have formed rapidly, and not allowed time for the heart to accommodate itself to this sudden encroachment upon the sphere of its operation; and it would be a more frequent occurrence if the strength of the heart were not weakened by this organ sharing in the muscular atrophy incidental to the disease.

The next source of hemoptysis is a tubercular excavation. In several phthisical patients who have died of hemoptysis, there have been found large excavations hollowed out in the lungs, and filled with blood either fluid or clotted: in this case the blood is also found in the bronchi and trachea, and the individual seems to have died of suffocation. It is very common to find the purulent matter contained in a cavity tinged with blood. It sometimes happens, though rarely, that the blood in these cavities is poured out from a vessel traversing their sides, in those transverse bands which Laennec has not unaptly com-

pared to the *carneæ columnæ* of the heart: these bands consist of an artery, vein, and bronchial tube matted together. The canal of the artery is generally obstructed, although an unhealthy inflammation pervading the pulmonary tissue will interrupt this provision of nature; and the arterial structure, which might almost be said to enjoy an immunity from the effects of inflammation under its ordinary circumstances, will here yield, and admit of an extravasation of blood.

The next *reputed* source of hemoptysis is the *parenchyma* of the lung. The lesion upon which this depends has, from its analogy with cerebral apoplexy, been designated pulmonary apoplexy. It is thought to depend upon a sanguineous exhalation into the pulmonary parenchyma, that is, into the air-cells, whose form is represented by the granular aspect of the surface of a section of a portion of lung affected with this modification of disease. This lesion, consisting of a circumscribed hardening of the pulmonary tissue, is considered by Laennec, who first noticed the subject, to be the frequent source of these alarming discharges of blood from the lungs which we sometimes meet with. The density of the affected portion of the lung is greater than that which constitutes hepatization. The hardened portion, different from that affected with hepatization, presents no trace of the pulmonary tissue, but is of a homogeneous aspect and of a deep black colour, resembling a clot of venous blood. Pulmonary apoplexy would seem to consist in a double lesion, viz. hemorrhagic engorgement and hemoptysis: this latter, though the most striking feature of the disease, is less essential than the other, and may be absent without changing the character of the lesion. Experience has established this fact, auscultation recognizing the engorgement which had not been announced by the ordinarily accompanying hemoptysis. Nor indeed have we much difficulty in explaining this, if we revert to the observations we made upon the freedom of communication between the pulmonary and bronchial vessels. It is found to occur most commonly from hypertrophy of the right ventricle; the effect of which lesion is to throw the blood with unusual force into the capillary vessels of the pulmonary artery. Should that force be considerable, the blood will not only pass into the bronchial capillaries, and thus into the bronchial tubes, giving rise to hemoptysis in the common form, but may lacerate not only the tissue of the lung, but also its investing membrane, and be extravasated into the cavity of the chest. We can likewise understand how the blood may be impelled with a force only sufficient to fill the capillaries of the pulmonary artery, without that force carrying it on to the bronchial capillaries; in which case we shall only have so much of the lesion as consists in the hemorrhagic engorgement without the hemoptysis; whereas, should the influence of this force extend to the bronchial capillaries, ordinary hemoptysis will be superadded. The external hemorrhage, then, we do not regard as a consequence of the hemorrhagic engorge-

ment, but as a concurrent effect of the same cause.

There is a species of pulmonary apoplexy in which the extravasated blood forms a coagulum in a cavity hollowed out in the substance of the lung. This is the only lesion which in strictness seems entitled to the designation of pulmonary apoplexy, as being that which alone is analogous to the condition of the brain in the true apoplexy of this organ. In this lesion the pulmonary tissue is lacerated by the blood issuing from its vessels, in the same way as the cerebral tissue is lacerated under similar circumstances. A case of this nature fell under our notice not very long since; the subject of it died of a profuse expectoration of putrid blood; and on examination after death a considerable quantity of blood in the same state was found in a cavity occupying the entire extent of the right lung. The attack arose from exposure to cold when the individual was in a state of intoxication.

The modification of pulmonary disease which Bayle has designated *ulcerous phthisis* (*phthisis ulcereuse*), and which is now recognized as gangrene of the lungs, from the fetor of the breath and expectoration which accompanies it, often gives rise to hemoptysis to such a degree as to cause death. Though this form of disease is sometimes, nay often, complicated with tubercular developments, the latter are not essential to it; it is, in fact, an unhealthy inflammation of the pulmonary parenchyma, which generally takes place in a bad habit of body, and in its destructive operation respects no tissue. This is the case in which nature seems to neglect her usual precautionary measure of obliterating the canal of the arteries, to provide against hemorrhage; these vessels remaining pervious, and giving way to the disorganizing ulceration, furnishes one of the few instances of hemorrhage arising from actual lesion of the containing canals. A profuse hemoptysis is often one of the first symptoms that ushers in this disease; but in general the patient for some time previously has had a pain in the side, and a teasing irritating cough, his general health much deranged, languor and lassitude, loss of appetite, &c. Amidst these symptoms he is sometimes suddenly seized with hemoptysis so extensive as to extinguish life at the moment; an instance of which is related by Bayle in the first case which he gives of this modification of disease.* In some cases the hemoptysis has the effect of relieving the system, as it were, from an oppressive load, and the patient feels himself much better after it; but fetid expectoration soon succeeds, and the hemoptysis is repeated at variable intervals, but with the same feelings of momentary relief. This state of things sometimes continues through this often protracted form of disease. Examination after death exhibits the several tissues of the lung indiscriminately involved in one general sloughy mass emitting an intolerable fetor.

* Observation 25.

Hemoptysis has no necessary connexion with pneumonia; the prune-juice sputa, however, which Andral regards as characteristic of the third stage of pneumonia, owe their colour to the blood, which is mixed with the other matter of expectoration. Bronchitis, especially when it occurs as an epidemic, is sometimes attended with abundant hemoptysis. This form of disease seems to differ much from ordinary bronchitis, and to bear some analogy to dysentery; for as this latter often degenerates into diarrhoea, so the former terminates in an analogous form of disease, consisting in a thin, frothy, abundant expectoration. When bronchitis thus occurs as an epidemic, it is accompanied with a small feeble pulse, great prostration of strength, loss of appetite, languor, lassitude, loaded tongue, and high-coloured urine, &c. It is of the last importance that we be acquainted with the form of disease, and be enabled to recognize the hemoptysis as a symptom connected with and dependent upon a serious constitutional derangement, and whose treatment merges into that of the constitutional disorder. We have known death to follow a mode of treatment which only contemplated the hemoptysis, and left out of sight the more important cause upon which it depended; this seems to be the disease which Stoll designated bilious hemoptysis, and which he treated so successfully with emetics.

Independently of organic lesion of the lungs, hemoptysis may arise from lesion of either the larynx or trachea, and is met with in persons whose profession requires a continued exercise of voice. Hemoptysis, however, from this source has been admitted more from analogy than from actual observation, and seems to rest more upon negative than upon positive evidence; more upon the absence of the signs of pulmonary hemorrhage, than upon any unequivocal proof that the blood comes from the larynx or trachea.

External injury often produces aggravated hemoptysis: thus, violence directly applied to the chest will sometimes be followed by an immediate and abundant expectoration of blood, an effect which is often attributed to an opening of some vessel produced by a fractured bone, which is sometimes one of the consequences of this violence; but as in many cases the hemoptysis comes on independently of any fractured bone, it must be ascribed to the commotion of the system produced by the violence. The assassin's poniard is the frequent source of fatal hemoptysis. Henry the Fourth of France received two strokes of a knife from the hand of the traitor Ravillac; he uttered a few words, threw up some blood, and immediately expired. Examination after death discovered two wounds: one, in the left side of the chest, did not penetrate; another, between the fifth and sixth ribs of the same side, penetrated the left lung, and made an opening to the pulmonary vein, capable of receiving the point of the little finger: the lungs were black and gorged with blood, and there was much blood effused into the cavity of the chest.

Treatment.—Having considered the important phenomenon of hemoptysis under its

different phases, and under the different circumstances both of the constitution and of the organs with which it is connected, we next come to the interesting subject of its treatment; upon which were we to enter as fully as its importance deserves, we should extend this article beyond its legitimate limits, and encroach upon other articles which have to deal with this phenomenon in the relation of a symptom of many morbid conditions both of the constitution and of the organs from whence the blood proceeds. To the several specific articles upon these morbid conditions we would refer for more detailed information upon this important subject, while our observations partake more of a general character. We have seen that hemoptysis generally occurs either in consequence of congestion of the lungs, or of lesion of these organs: what we shall have to observe upon its treatment will contemplate it under these two modifications of circumstances.

Congestion of an organ so important as the lungs must ever be regarded with alarm, and for this reason Hoffmann observes that of all morbid hemorrhages hemoptysis is that which is accompanied with most danger. Even when it is connected with suppression of some habitual discharge, and seems to make amends to the constitution for the derangement of its functions, it cannot with safety be permitted to continue, but must be met with an uncompromising hand.

The treatment of hemoptysis resolves itself into that which is to be employed during an attack, and that which is to be pursued in the intervals of the attacks, with a view to prevent their return. The character of the hemorrhage, as to its active or passive nature, is the point upon which the treatment hinges. In an attack of active hemoptysis, general bleeding, proportionate to the vascular organism and to the strength of the individual, must be employed, and leeches should be applied to the chest, or in the neighbourhood of the organ which is the usual vent of the hemorrhage upon whose suppression the hemoptysis may depend. The auxiliaries to bleeding are derivatives or counter-irritants, either internal or external. The first include purgatives, emetics, sudorifics, and diuretics; in fact, all those medicines which, exhibited internally, produce a derivation to counterbalance the original hemorrhagic movements. The external counter-irritants consist of blisters, mustard cataplasms, frictions, and rubefacients, &c. Among the internal derivatives, purgatives of the saline class hold a foremost place; while they determine to the mucous membrane of the intestinal canal, they reduce the mass of the circulating fluid. Emetics present the threefold advantage of causing a revulsion, of producing a sedative effect upon the heart, and of determining to the skin. Sudorifics and diuretics also produce a derivative effect (though in a milder degree) by their action upon organs different from that which is the source of the hemorrhage. Nitre, from its refrigerating properties, has been long regarded as a most valuable medicine in active hemorrhage: it has

been reputed to produce an actual change in the inflammatory character of the blood. Digitalis and acetate of lead powerfully co-operate to restrain the violence of the heart's action by their sedative effect upon this organ. Muriate of soda is a popular remedy for hemoptysis, and one whose efficacy we have often witnessed. Acidulated drinks are valuable adjuvants.

Much difference of opinion prevails as to the place where external counter-irritants may be applied with most advantage; some recommending the nearest point to the seat of the congestion as the fit place for their application; while others prefer a distant point, a preference to which we subscribe, both from reason and experience. The nervous agitation which generally accompanies hemorrhage suggests to us the absolute necessity of repose of both mind and body. There should be a free circulation of cool air around the patient, but not so cold as to cause constriction of the skin, and thus determine to the internal organs. The diet should be conducted upon the most rigid principle of abstinence from every thing capable of producing the least excitement of the system.

It will sometimes happen that the hemorrhage will reduce the powers of life so low that we shall be obliged to administer stimulants. The proper management of a patient under these circumstances is one of the nicest points in the practice of medicine, as we have to determine the extent to which we can safely employ stimulants without running the risk of exciting the system, and awakening the orgasm which has produced the effect which we seek to redress. In many of these cases there is no proportion between the loss of blood and the constitutional disturbance, the latter being much greater than can be accounted for by the actual hemorrhage, which is sometimes very inconsiderable: the nervous irritability of the individual can alone account for it: here we may advantageously employ antispasmodics, viz., camphor, ether, &c. to calm the flurry and agitation of the nervous system.

If the hemoptysis, *ab initio*, partake more of a passive character, we shall find our most valuable remedies to consist of the mineral acids, conserve of roses, infusion of roses acidulated with sulphuric acid, turpentine, muriated tincture of iron, &c., and sponging the chest with cold vinegar and water. To these cases much advantage is derived from blisters applied to the chest; they restore the tone of the capillary vessels, upon whose weak condition the hemoptysis depends. A free circulation of refreshing air is no less beneficial in passive than in active hemoptysis: we have known it to give an immediate check to this affection. We are not obliged to observe the same strictness in diet in this form of hemoptysis, and may gradually come to that of a more nourishing character, with a moderate use of port wine and water.

We are next to consider the treatment and management of hemoptysis in the interval of the attacks, with a view to prevent their recurrence. If we can connect the hemoptysis with

the suspension of an habitual hemorrhage, the obvious indication is to restore that hemorrhage. Should a suppression of the hemorrhoidal discharge be the cause, aloetic purgatives, and leeches applied *circa anum*, are the means to be employed. If the suspended menstrual discharge seem to be the cause of the hemoptysis, we must endeavour, though with caution and without forcing the system, to restore the due order of the functions; and with this view we try to assist the abortive efforts of nature at the ordinary period of the menstrual discharge, by determining to the uterus by means of aloetic purgatives, by leeches applied to the interior of the thighs, and by the hip-bath: but our treatment will especially consist in imparting a degree of vigour and tone to the constitution, upon a deficiency of which this derangement of function often depends. In this case chalybeate tonics furnish us with a valuable resource: sea-bathing, horse exercise, &c. also assist the object we have in view. (See AMENORRHEA, CHLOROSIS, EMMENAGOGUES.)

In some cases we meet with this morbid phenomenon in a condition of the system precisely opposite to that which we have just described, and in which we have to adopt a mode of treatment and management as opposite. In this latter instance our object is to reduce the fulness and plethora of the system by medicine and diet.

Should the cause of the hemoptysis be less obvious, the frequency of its association with phthisis, and its being so often the precursor of this fatal malady, must make us ever regard it with alarm. We before remarked that the adjustment of the question as to tubercles being the cause or consequence of hemoptysis was a matter of indifference as regarded the treatment to be adopted to combat this affection; for, as Laennec has observed, it must be met by bleeding carried to the very limits of possibility. The question, however, assumes an aspect of greater importance when we come to consider the treatment suited to the intervals of the attacks of hemoptysis: we then feel that it involves a consideration of the most vital moment, how far we can with safety pursue a depletory mode of practice, which may have the effect of indirectly generating tubercles, by producing a habit of body favourable to their development.

The formation of tubercles seems to us to be, in most cases, the result of a deteriorated constitution taking on an action *infra se*. We meet them either in persons imperfectly nourished, or in those who have been wasted by previous disease, as by long protracted fever. We have observed in phthisical patients a disposition to generate worms and vermin, even in those who, to the latest moment of their existence, bestowed the utmost pains on the cleanliness of their person. The inference we deduce from this is, that these parasitical animals, like tubercles, indicate a degeneracy of habit, or, so to speak, a descending in the scale of the animal being. These points, however, more properly belong to the articles

TUBERCLES and PHTHISIS, to which we refer for more detailed information upon them. We would only observe that the causes which call a tubercular diathesis into active operation are such as have the effect, either directly or indirectly, of debilitating the energies of the constitution; and that therefore, though hemoptysis be a complication with which we cannot tamper, but which we must meet with decision, we cannot but regret the dilemma in which we are placed by a symptom requiring a mode of treatment which we have reason to apprehend may have the effect of increasing that condition of the system which has given rise to the original disease. We would convey our opinion respecting bleeding in phthisis in the words of Laennec, who observes that as bleeding can neither prevent the development of tubercles, nor cure them when they are formed, it should not be employed in the treatment of phthisis, except with a view to subdue an inflammatory complication or acute sanguineous congestion; beyond this it is a gratuitous waste of the patient's strength, and may be superseded by medicines, which have the effect of reducing the powers of the circulation without producing permanent prostration, such as digitalis, tartar emetic, &c. We would here express our decided conviction that phthisis, of which hemoptysis is so frequent a symptom, would be treated with much more success if physicians were not continually haunted with the apprehension of exciting or keeping up inflammation; a feeling which, within due limits, should ever be present, but still when pushed too far, and acted upon too rigorously, it deprives the system of its remaining stamina, and unfits it for bearing the exhausting effects of a wasting disease. A gentleman in Scotland (Dr. Stewart), who has now ceased to be a member of the medical profession, long since ventured to deviate from the routine of practice in this disease, and pursued a mode of treatment which has had most encouraging success: the principle of this treatment was to strengthen the constitution. He argued, that when the tubercles softened and the expectoration became purulent, the treatment should be the same as that required by the formation of matter in other parts of the body, when we have no other view than that of supporting the system. To fulfil this intention he treated the disease with tonic medicines cautiously exhibited, but placed his chief reliance upon cold bathing, exercise, and nourishing diet. His plan with respect to cold bathing consisted in making the patient sponge the entire body in the morning, and the neck, chest, and shoulders at night, with tepid vinegar and water, whose temperature was reduced each day till it was quite cold: this sponging was followed by rubbing for half an hour with flannels, and then with a flesh-brush. By degrees, as the feverishness subsided, the vinegar was laid aside. This was a preparation for cold bathing, and afterwards for sea-bathing. We do not mean to affirm that tubercles do not often form in an inflammatory habit, and that bleeding is

not often required in such a habit; we only question its propriety as a preventive measure.

The slighter hemoptysis, which comes on in the progress of consumption, seldom demands constitutional bleeding: it will in general be checked by acetate of lead, nitre, digitalis, conserve of roses, acidulated drinks, &c.

When the frequency of hemoptysis in an individual not naturally predisposed to phthisis leads us to connect its cause with some obscure condition of the capillary vessels of the organ exhibiting itself in either active or passive hemorrhage, we have to treat it as an idiopathic disease, and not, as before, as a symptom whose treatment was modified by that of the disease upon which it depended. The character of the hemorrhage, whether active or passive, alone regulates our attention: we are, therefore, relieved from the caution with respect to bleeding which tied up our hands in the management of this morbid phenomenon in phthisis. It was this kind of habitual hemoptysis to which we before alluded, as deriving so much benefit from small bleedings often repeated; a practice which seems to us entitled to a decided preference over large bleedings which cannot be repeated: for the efficacy of bleeding in these cases depends not so much upon the quantity of blood drawn, as upon the revulsive effect of the operation; the opening in the vein solicits the blood to it, and so diverts it from the source of the hemoptysis. The older physicians appreciated this point of practice, and accomplished it by closing the opening during the operation. When we reflect how comparatively independent of the general circulation the capillary system is, we see reason to expect more advantage from means which have more of a local operation, as cupping, leeching the chest, &c. We shall find nothing to exercise such a salutary control over this kind of hemoptysis as change of air, adapting the temperature to the character of the discharge; if it be active, removing to a warmer climate; if passive, to a colder and more bracing. This hemorrhage is much influenced by moral causes; moral management constitutes an important part of its treatment: the writer has known it to cease immediately upon hearing agreeable news.

Pulmonary apoplexy demands full depletion. Bleeding should be carried to the extent of producing fainting; and should the hemoptysis still continue, we must adopt every other means calculated either directly or indirectly to lower the energies of the circulation. For this purpose we would employ small doses of ipecacuanha often repeated, so as to keep up a continual nausea. Purgatives are a valuable resource. Laennec has not found tartar emetic as beneficial in this form of disease as in inflammation. Astringents should not anticipate the chronic stage of the disease.

Hemoptysis dependent upon gangrene of the lungs requires a mode of treatment adapted to the vitiated constitution in which it occurs. Tonics constitute our principal remedial agents, while we seek to allay the irritation of the cough by opium, hyoseyamus, conium, &c.

When hemoptysis proceeds from the larynx or trachea, and seems to be produced by an excessive exercise of voice, the first thing required is the repose of the organ; nor, in general, is this enough; as the local affection is merely the index of constitutional relaxation, the object of the means we employ must be to restore the tone of the system by exercise, shower-baths, sulphate of quinine, &c. To this we would add sponging the throat with vinegar and water. For further information on this subject we would refer to the articles APOPLEXY PULMONARY; PHTHISIS PULMONALIS; LUNGS, GANGRENE OF THE, &c. &c.

(Robert Law.)

HEMORRHAGE, (*αιμορραγία*, from *αἷμα*, *sanguis*, and *ῥήγνυμι*, *rumpo*), loss of blood. The purpose of this article is to present a summary view of the knowledge we possess, and of the doctrines now generally received, concerning *internal hemorrhage*. The term is here employed in its most comprehensive sense, as signifying the passage of the blood beyond its natural channels—beyond or out of the vessels that are appointed to contain and convey it in the healthy living body. Under this definition it is indifferent whether the extravasated blood remains pent up within the body or not.

The epithet *internal* is however prefixed, in order to limit the subject to those forms of hemorrhage which fall within the province of the physician, and to exclude all consideration of those cases which, whether they are the result of disease, or of accidental injury, or of surgical operation, are capable of relief by mechanical expedients only. These latter cases are sometimes, though not perhaps with much propriety of language, comprised under the general title of *surgical hemorrhage*, in contradistinction to the former, which are then classed as being *medical*.

In what has been called surgical hemorrhage the blood proceeds from some large vessel, situated within the reach of the eye and the finger. The principles upon which the loss of blood in such cases is arrested or prevented are well understood; and in no part of the rapid progress of modern surgery has the union of well contrived observation with sound reasoning been productive of more admirable results. With a few remarkable exceptions, such as the protection afforded against small-pox by vaccination, or against sea-scurvy by the use of lemon-juice, there is not perhaps any single improvement in the art of healing by which so many lives are saved, and so much human suffering is relieved or averted, as by the scientific application of the ligature upon the larger bloodvessels.

That kind of hemorrhage which falls to the care of the physician is less perfectly understood, and is controllable with less certainty. It comprehends, however, a large and very formidable class of diseases. In some of these the effusion of blood is an accidental symptom only; of many it forms the principal sign or

circumstance; and there are others in which it may be considered, in reference to our united means of investigation, as constituting the whole disease.

The accidental injuries to which the animal frame is continually exposed must have furnished mankind, from the earliest times, with frequent illustrations of the striking fact that the mere loss of blood, when it exceeds a certain amount, implies also the loss of life. They who had seen their fellow-men bleed rapidly to death from external wounds would be strongly impressed with the great importance of the fluid, the removal of which from the body led to an event so appalling; and they would look with interest and alarm upon the rarer instances which might occur of bleeding from internal and unseen parts. A natural but deceptive analogy, uncorrected by pathological knowledge, would almost unavoidably lead them to this further inference, that *all* hemorrhage—hemorrhage, the source of which they could not see, as well as that the source of which they were able to examine and appreciate,—proceeded from an opening in the sides of some one (or more) considerable blood-vessel.

It is true that some hemorrhages, of which the origin is, during life, beyond our vision and means of inquiry, do result from the rupture of vessels of a certain magnitude; but it is no less true that in the greater number of instances of bleeding from the interior of the body, there is no lesion, capable of being detected by dissection, either of the veins or the arteries; but the blood is poured out by what is called exhalation, and proceeds from those ultimate ramifications of the minuter blood-vessels which constitute the capillary system.

This remarkable and important piece of knowledge was ascertained long since by Morgagni; it was more formally and completely demonstrated by Bichat; and it has been so amply illustrated by subsequent observation that it may seem to be a fact almost too trite to dwell upon. Yet, judging from the writings and language even of medical men, it does not appear to be so generally known or acknowledged as it ought to be among *them*; and among unprofessional persons the old errors upon this subject prevail almost universally. To break or burst a bloodvessel, in the most literal meaning of those words, is thought by the public, and by some at least of the profession, to be a misfortune of very common occurrence; yet relatively to the frequency of hemorrhage, it is certainly a very rare one.

Bichat explicitly propounds the doctrine that in certain hemorrhages the blood escapes from the capillary vessels by a process which, in pursuance of his example, and to avoid circumlocution, we shall call that of exhalation. He rests this opinion upon several distinct considerations, some of which are perhaps more curious than conclusive.

Thus he states that if the uterus of a female who has died during the menstrual period, be carefully examined, no erosion of its inner sur-

face or of its bloodvessels can be seen, nor any of those numerous cicatriculæ which, he argues, must have been formed, if each occurrence of the catamenial discharge had resulted from a rupture of those vessels.

The rupture which he here supposes is the simultaneous laceration of numberless capillary bloodvessels. Such laceration, if it took place, would indeed account for the discharge; and it has been assumed in explanation of some morbid hemorrhages. It is by no means certain, however, that it would give occasion, especially on a mucous surface, to visible scars. Punctures, even of the skin, made by fine needles which wound the bloodvessels, do not, we imagine, however numerous they may be, leave any such traces of their former presence.

He adds, that if we submit the same uterus to pressure, and mark closely what happens, we see minute drops of a red fluid exude from its inner surface; and if we then wipe these drops away, the membrane whence they proceeded appears to be perfectly entire.

Whatever weight this argument may possess is strengthened by the actual observation of the process of menstruation in the living uterus. Dr. James Hamilton of Edinburgh is in the habit of relating, in his lectures, the case of a patient who was once under his care, and whose complaint appeared to him so instructive upon this very point, that he sent her into the clinical wards of the infirmary, that the students might have an opportunity of witnessing it. This woman was afflicted with enlargement and complete prolapsus of the uterus. The professor describes the inverted womb as having hung down between her thighs like a quart bottle; it could not be replaced; and it was tense and hard, except during the periods of menstruation, which took place regularly. At those times it became soft and flexible, and the menstrual discharge was seen, by numbers of medical men and of students, to issue *guttatim* from the exposed surface.

As, however, the process of menstruation cannot be looked upon as a morbid process; as, in the unpregnant female, during a certain portion of her life, it is not only consistent with perfect health but actually essential to it; and as the fluid so poured out is not strictly blood; the analogical argument drawn from the preceding facts in favour of hemorrhage by exhalation, though it may afford a strong presumption, is not decisive.

But the deficiency here noticed is supplied by what is observed in those cases (rare indeed, yet well authenticated) of actual cutaneous hemorrhage, where a dew of blood appears upon some portion of the skin, is wiped away, and reappears, with no perceptible alteration of the affected surface beyond some occasional variation in its colour.

Another of the arguments advanced against the possibility of rupture or laceration in such cases is drawn from the well-known fact that the flow of blood, or of the catamenia, will sometimes continue for a few moments, then cease, and again recur; and that these alter-

nate changes may happen several times in the course of a single day; so that, upon the supposition against which Bichat is contending, the wounds of vessels must heal and re-open at every change.

This reasoning is obviously both inconclusive and erroneous. We know that the cessation of hemorrhage from a *torn* vessel may and often does result from other causes than cicatrization; that even when the vessel is of considerable size, and the laceration extensive, the bleeding may occur, and pause, and occur again, and that repeatedly, within a short space of time.

Bichat did not overlook that species of evidence by which alone, after all, the existence of hemorrhage, independent of any rupture of vessels, can be satisfactorily established. He states that he had frequently dissected the bodies of persons who had died from hemorrhage; that he had examined, according to the nature of the case, the surfaces of the bronchi, the stomach, the intestines, or the uterus; and that, although he took the precaution of washing them clean, and even of submitting them to maceration before he inspected them with a microscope, he never could detect the slightest appearance of erosion.

Numerous and conclusive observations of the same kind have been accumulated by the zealous pursuit of morbid anatomy for which the present age is so remarkable; and in this way direct proof has been obtained, not only that internal hemorrhage may take place from the surfaces of membranes by exhalation, but that this is the mode in which it most commonly happens; that the effusion of blood by any of the natural outlets of the body can seldom, excepting in the cases of aneurismal disease, be explained by the detection of a broken bloodvessel.

Where hemorrhage, for example, has occurred so profusely from the stomach or bowels that the death which ensued has been sufficiently accounted for by the mere loss of blood, the whole tract of the alimentary canal has been diligently scrutinized, and has exhibited no breach of surface, nor any perceptible alteration of texture. Sometimes its mucous membrane appears, here and there, of a red colour, and as it were charged with blood; sometimes it is pale and transparent, while the vascular network visible immediately beneath it is gorged and turgid; sometimes the whole is colourless, the same network of vessels having been completely emptied by the previous hemorrhage; and sometimes again (and this is very illustrative of the mode by which the blood has issued) vast numbers of small dark-coloured masses, like grains of fine sand, can be made to start from the surface of the membrane by slight pressure. There can be no doubt that these are minute portions of blood, which had remained and coagulated in the vessels or apertures forming the ultimate channels of the hemorrhage.

These views receive an indirect but strong support and illustration from the well-known circumstance, that certain hemorrhages are pre-

ceded and followed by an increased efflux of the fluids which belong to the surface concerned. In hemorrhages from the mucous membranes this succession of events is in some persons habitual. First there is an augmented flow of mucus alone, then of mucus tinged with blood, then of blood alone; and the hemorrhage ceases by a similar but inverse gradation towards a mucous drain, which itself at length decreases and disappears. In such cases (there being no manifest erosion or organic change) it is apparent that the blood proceeds from the same vessels or apertures, which in health pour out the natural fluids of the part—mucus, serum, or sweat. There seems no more necessity, under the action of disease, for a rupture of vessels to give exit to the blood than to give exit to these fluids. What the vessels or outlets to which we give the name of exhalents really are—how they are distributed and arranged—in what manner they are connected with the ordinary capillary circulation of red blood—or under what influences they are placed—are points concerning which we have little or no certain knowledge. We know indeed that such channels must exist, though we cannot demonstrate or see them; and that, whilst the health is entire, they do not allow the blood, as such, to pass through them.

Several kinds of hemorrhage by exhalation have been enumerated by pathologists, according to the different morbid conditions with which the efflux of blood is associated. The chief distinctions of any importance may, however, be almost all comprised within the two general classes of *idiopathic* and *symptomatic* hemorrhage.

Idiopathic hemorrhage is that which occurs without any discoverable change of texture, either in the part from which the blood proceeds, or in any other part capable of influencing the circulation in the former, by reason of some intelligible connexion of structure, or function, or mutual relation. The epistaxis of young persons affords an example of this kind of hemorrhage, to which the terms *spontaneous* and *essential* are also sometimes applied.

Symptomatic hemorrhage, on the other hand, is that which depends upon some notable organic disease. It comprehends all cases of hemorrhage by exhalation not embraced by the definition just given of idiopathic hemorrhage. It may be said to be *primary* when the organic disease upon which it depends is situated in the very part which gives issue to the blood; *secondary*, when the organic disease is situated in some other part more or less distant from the former.

We have instances of the primary species in hemorrhage from the stomach, or from the uterus, dependent upon incipient scirrhus of those organs; from the pleuræ or peritoneum, under violent inflammation; from the mucous membrane of the air-passages in intense bronchitis.

Examples of the secondary species occur in hemorrhages from the bronchial membrane in

consequence of the presence of crude tubercles in the lungs, or of organic disease of the heart; and in hemorrhages from the mucous membrane of the stomach and bowels in consequence of disease obstructing the circulation through the spleen or liver.

The proximate cause (as it is called) of idiopathic hemorrhage—or the essential condition of the facts concerned in its production—is involved in much obscurity. There appears good reason for believing that it is different in different cases. It is certain that in very many instances the hemorrhage is preceded and accompanied by an unusual accumulation of blood in the capillary vessels of the part. In the secondary species of symptomatic hemorrhage this kind of sanguine congestion is also almost always present, and is then owing to some mechanical impediment of the venous circulation. The causes of such congestion antecedent to idiopathic hemorrhage are less obvious, especially when the congestion is partial.

Since the time of Stahl and his disciples the existence of local plethora has been fully recognised as constituting a frequent element of disease. Some of the distinctions introduced by him were doubtless fanciful: it is certain, however, not only that local congestion is of common occurrence, but also that this unequal distribution of the blood in the capillary vessels may happen in several ways, and from various causes, easily distinguishable from each other. M. Andral, the most recent, and probably the most able writer on this subject, describes three different conditions under which local plethora (or, to use his own convenient though somewhat uncouth phraseology, *hyperemia*) may occur in the living body.

One of these conditions has been already adverted to, that, namely, in which the return of the blood from the capillary vessels towards the heart is impeded by some mechanical obstacle. Hyperemia of this kind may be strictly local. It may be confined to a single limb when the principal venous trunk belonging to that limb is compressed, or otherwise diminished in size. If there be disease of the liver, of such a nature as to prevent a free passage of the blood through that organ, congestion will take place in all those parts of the capillary system from which the blood is conveyed by the veins that ultimately combine to form the vena portæ. The force of gravity alone will be sufficient to induce venous congestion in parts of the body in which, under ordinary circumstances, the circulation through the veins is aided instead of being opposed by that force. If the head, for instance, be suffered to hang downwards for a certain time, we see the unequivocal signs of such congestion in the tumid condition and the purplish colour of the lips, cheeks, and eyelids. When an impediment to the free transmission of blood exists in the heart itself, a tendency to stagnation is produced, first in the venæ cavæ, then in the smaller ramifications by which these veins are fed, and at length in the general system of capillary vessels; and thus general hyperemia

from a physical cause will ensue, the parts which are the most vascular being also the most readily and the most completely gorged.

The two other forms in which local plethora or hyperemia may present itself are called respectively active or sthenic hyperemia, and passive or asthenic.

The first of these proceeds from some irritation or stimulus, either applied to the part itself, or influencing that portion of the nervous system by which the vital actions of the part are regulated.

The irregular distributions of blood which fall under this head are not always morbid. In a certain degree and for a certain time they may consist with the most perfect health. The deep flushing of the cheeks and forehead under strong mental emotion, and the general redness of the skin produced by violent exercise, are familiar illustrations of this healthy congestion of capillary vessels. A similar congestion may be produced at will upon the surface of the body by mechanical or chemical stimuli—by friction for example, or the application of heat. If these causes of the local accumulation of blood be intense in degree, or continue to be applied for a certain time, the congestion is accompanied by disturbance of the functions of the part—by pain, or by other well-known changes.

But local congestion of this active kind, and essentially morbid in its character, is of frequent occurrence in various organs of the body; and in many of these cases there is no obvious exciting cause of such an unequal distribution of the blood. We have evidence indeed, in the blush of shame or anger, and in the paleness of fear, that the capillary bloodvessels may be filled to excess, or completely emptied, by causes operating through the brain and nerves; and it seems probable that morbid congestions, which are sometimes separated from those consistent with health by shades of difference not easily discriminated, may also be occasioned through the agency of the same nervous system.

Local hyperemia of the active kind seems in many instances to form a part, or rather to be an effect, of a plethoric condition of the whole body. To understand precisely what is meant by a state of general plethora, it is necessary to remember the physiological doctrine that the whole vascular system is constantly distended beyond the size of the vessels when free from any distending force. When the arteries are in any way emptied of their contents, their diameter diminishes, and frequently they become even impervious. The general notion of plethora is that this state of distention is greater than what is ordinary or natural. It is easy to conceive that in persons who live fully, lead an inactive life, and sleep much, there should be a greater quantity of blood formed, and consequently a preternatural distention of the vessels. Fulness of habit and a florid complexion are marks of the existence of general plethora; of superfluous blood being partly expended in the formation of that substance which is the least necessary in the animal economy, namely, fat,

the capillary vessels of the face partaking of the general fulness or vascular distention present in all parts of the system. We trace the existence of general plethora also in the character of the diseases most prevalent in those who are the subjects of it, in the tendency especially which they evince to hemorrhage and to inflammation.

A state of general plethora is, however, by no means essential to the production of local congestion, which, on the contrary, is of frequent occurrence in persons who are pale, spare, and deficient in blood. Nay, a remarkable proclivity to an unequal distribution of blood in the capillaries, has been observed in those who, from accident or disease, have already lost large quantities of that fluid. The general symptoms, however, which accompany local hyperemia in these two opposite conditions of the system, undergo proportional modifications.

The simple existence of local congestion of the active kind, and independent of any mechanical impediment, is sufficient to show that the blood, after it has entered the capillary system, is no longer under the sole influence of the heart's impulse; but that its subsequent motion is mainly determined by a power of contraction belonging to the smaller bloodvessels themselves. It is upon a supposed defect of such power—a diminished tonicity of the vessels, that the doctrine of asthenic or passive hyperemia is founded.

The efficacy of the assigned cause in the production of hyperemia is perhaps less obvious here than in the cases which have just been considered. The following are some of the observed facts from which its actual operation has been presumed.

In persons enfeebled by age or by disease, the lower parts of the legs, the ankles, and insteps, and the skin which forms the surface of old scars, are often habitually purplish or violet-coloured. This cannot be owing to the mere influence of gravity, because that remains constant at all ages and in all conditions of the system. The peculiar colour, denoting a sanguine congestion of the part in which it is visible, may indeed be diminished sometimes by placing the limb in the horizontal position, whereby the weight of the blood in opposing its own return from the capillary vessels being removed, the action of the vessels themselves again suffices for its propulsion. But the congestion in these cases often disappears upon the employment of friction, or of stimulating application, which would be powerless against any mechanical obstacle in the larger veins, and which would tend to increase the afflux and accumulation of blood in active hyperemia.

In the same way the large, flabby, and livid granulations which often appear on the surface of indolent ulcers, are made to contract, and to assume a more healthy and florid hue by local stimulants, which quicken the previously languid circulation by exciting (it is supposed) the vital action of the minute bloodvessels.

There is no part of the body which affords more striking and unquestionable evidence that

blood may accumulate unequally in the smaller vessels, than the eye. The conjunctiva and sclerótica, through which, while healthy, colourless fluids alone circulate, are traversed, under various forms of disease, by innumerable vessels bearing red blood. It is notorious that in certain cases the application of any stimulant to the surface of the organ will increase the existing redness, multiply the number of visible vessels, and aggravate the disease. These are cases of active hyperemia, dependent upon irritation which is still subsisting. It is equally well known that the same vessels are liable to congestion under very opposite circumstances. They are then seen to be distended with blood, tortuous, and varicose; and the redness is browner, and less vivid than before. In this kind or stage of vascular fulness, emollient applications do harm rather than good; while strongly astringent and even highly irritant substances will often promptly dissipate the vascularity. There are, again, cases illustrative of hyperemia of the asthenic kind. The strong topical irritants restore the feeble and relaxed vessels to their natural elasticity, stimulate them to contract upon their contents, and to force onwards the blood, which they cease to admit from the arteries, and the redness disappears.

In the examples here touched upon, the asthenic character of the local congestion is denoted by the peculiar aspect of the altered parts; by the circumstances under which the congestion happens; and, above all, by the nature of the measures which conduce to its removal. The doctrine of asthenic hyperemia admits of extensive and most important application, in regard to various internal morbid conditions of the body. But any further prosecution of this part of the subject would be irrelevant to the present inquiry. The preceding observations have been made with the view of demonstrating or of rendering probable certain differences in respect to the manner in which the capillary bloodvessels may become unequally loaded, and of elucidating thereby some of the modes of hemorrhage; of showing in particular that a predisposition to hemorrhage may arise under very different conditions; that it is far from being always of one and the same character, or susceptible of relief by the same kind of treatment. The fact, then, which is beyond dispute, of the frequent pre-existence of local engorgement and distention in the capillary circulation, gives support to the hypothesis that (in certain cases at least) the issue of blood results from pressure, whereby the blood in substance is urged through passages naturally impermeable by its red particles, but now mechanically dilated in consequence of the *vis a tergo*. Although the dilatation cannot be made sensible to the eye, this seems the simplest and most obvious explanation applicable to some forms of idiopathic hemorrhage, and to the secondary species of that which is symptomatic. That blood may be thus exhaled, independently of any disease in the vessels themselves, we know from experiments made on animals, and from the ob-

servation of what sometimes occurs in the healthy human body. Boerhaave produced hemorrhage into the intestinal canal of a living dog, by placing a ligature on the vena portæ. An extreme turgescence of the whole venous system is one of the results of sudden strangulation. Dr. Yelloly accordingly found such turgescence conspicuous in the bodies of five criminals who had recently suffered death by hanging; and in two of these instances, blood in considerable quantity had exuded from, and coagulated upon, the mucous membrane of the stomach.

Hemorrhage has been ascribed also to some alteration (other than that which we may conceive to be produced by the distention of plethora) in the vessels or apertures through which the healthy exhalations are transmitted. The change is considered as being of the nature of morbid debility or relaxation. That such a state may sometimes exist is not unlikely; but as we are altogether ignorant of the natural condition of these outlets, it is difficult to reason about the alterations to which they may be liable in disease. This hypothesis derives its principal support from the occasional efficacy of astringent substances (either locally applied, or taken into the system) in checking the effusion of blood, when artificial bleeding has failed.

Another mode in which the occurrence of hemorrhage has been explained, supposes an alteration in the consistence or composition of the blood itself, which thus becomes attenuated, and capable of passing through channels or orifices that healthy blood cannot penetrate. In defence of this supposition are adduced the facts that hemorrhages are known to occur where the blood is obviously more thin, pale, and serous than common; and still more remarkably where that fluid has undergone a demonstrable change in its chemical nature, or is even visibly altered in its sensible qualities; as, for example, in certain cases of purpura and of sea-scurvy.

These hypothetical attempts to explain the processes by which hemorrhage may take place deserve, perhaps, more attention than has sometimes been paid to them. The views which they involve can scarcely be regarded as mere speculative refinements; for they often exercise a real, though perhaps an unacknowledged influence upon our practice. At any rate, if they do not, prior to experience, justify certain modes of treatment, they accord wonderfully with what experience has taught concerning the means by which hemorrhage may sometimes be stayed or prevented. In some cases we succeed by measures which tend to abate the general force of the heart and arteries and to lessen general plethora, or by diverting partial plethora and restoring the disturbed balance of the circulation, or by directly emptying the turgid capillary vessels. In other cases we rely chiefly upon expedients which we believed to have the effect of constricting the extreme vessels; styptics to the bleeding part, cold to the surface of the body, producing a sympathetic shrinking in other related

membranes; or internal medicines, which use has shown to have the property of restraining the natural exhalations when in excess. And, finally, there are cases where we seek, and not in vain, to repair the blood, to restore it to its natural condition by improvements in diet, or by food of a peculiar kind, such as the juice of lemons; and *thus* the tendency to hemorrhage is cured.

Whether the hypotheses originated from a contemplation of symptoms, or whether they were suggested by the apparent effects of remedies, may be doubted; but it is well worthy of remark how in the several cases they accord with both these classes of observed facts. Certainly hemorrhage is a prominent symptom in several morbid conditions, differing greatly from each other; and there is nothing inconsistent in sometimes attempting its explanation in one way, and sometimes in another.

One observation yet remains, in regard to this doctrine of a preceding turgescence of the minute bloodvessels; namely, that it applies not only to certain kinds of hemorrhage, but also to inflammation, of which indeed it appears to be a *constant* and necessary element. Why, in one instance, the congestion terminates in that complex and variable process, or why, in another, it is relieved by an effusion of blood, we hitherto know not; but the fact that the same condition of capillary plethora is inceptive sometimes of the one form of disease, and sometimes of the other, supplies a rational ground for the analogy which has often been traced between hemorrhage and inflammation; and, what is of no less importance, it points out also the boundaries within which that analogy should be limited.

There is a very ancient division of hemorrhage (into active and passive) drawn, not so much from the nature of supposed proximate causes, as from the assemblage of circumstances in connexion with which the efflux of blood takes place.

The distinctive characters of these two forms of hemorrhage are, in well-marked cases, sufficiently broad and decided.

Active hemorrhage occurs in persons who are young and robust, who live fully, and lead indolent lives, and are subject to the influence of those causes which tend to generate plethora. Occasionally the hemorrhage can be traced to some exciting cause, such as exposure to heat, strong mental emotion, or violent exercise. More frequently, however, it seems to be the consequence of the predisposing causes merely. It is sometimes announced by a set of symptoms expressive of what has been called the *molimen hemorrhagicum*. The patient experiences a general feeling of indisposition, with wandering and obscure pains that gradually settle in the part from which the blood is about to be discharged. A series of local symptoms, such as a sensation of weight, or of tension, or of heat and tingling, sometimes a slight degree of turgescence and redness, and a visible fulness of the larger veins, indicate the afflux of blood towards the labouring organ and the parts in its vicinity; while chilliness,

palleness, and shrinking of distant parts, and especially of the feet and hands, denote an opposite state of the circulation in *them*.

The blood commonly escapes with rapidity, is of a florid colour, proceeds from a single organ, and readily coagulates, though it seldom separates distinctly into serum and crassamentum. While it is flowing, the signs of local hyperemia diminish and disappear, warmth returns to the extremities, and the pulse regains its natural strength and frequency. The patient becomes conscious of a sensible relief, and feels stronger and more lively than before. This kind of hemorrhage is in some sort its own remedy; it ceases in virtue of the discharge of a certain quantity of blood, and it is followed by morbid consequences only when that quantity has been excessive.

Passive hemorrhage is characterized by circumstances of an exactly contrary nature. It occurs in those who are naturally feeble, or who have been debilitated by disease, fatigue, insufficient nourishment, great evacuations, or the depressing passions. It is not, in general, announced by any precursory symptoms, nor attended by any re-action. The effused blood is of a dark colour, serous, and but little disposed to coagulate; and it often is poured forth from several parts of the body at the same time. If the quantity lost be at all considerable, the natural debility of the patient is rapidly augmented; his face becomes pale, and his body loses its heat. The hemorrhage leaves him in a worse condition than that in which it found him. The flow of a certain quantity of blood is not, as in the cases of active hemorrhage, suspensive of its further effusion; frequently, indeed, passive hemorrhage resists the means opposed to it the more in proportion as it has continued longer, or been more profuse.

If every case of hemorrhage could be accurately referred to the one or the other of these forms, this distinction would be of the greatest importance and value. The truth is, however, that the majority of cases cannot be said to possess decidedly either an active or a passive character. The flow of blood is not preceded by any notable excitement or exhaustion, is not announced by any precursory symptoms, and is neither followed by any sensible improvement, nor (unless it exceed a certain limit as to quantity) by any marked debility.

May not this indefinite character of the majority of cases be accounted for by the consideration that most hemorrhages are in fact merely symptoms, and derive their character from that of the disease of which they form a part? Does it not appear that the distinction of active and passive applies chiefly to the smaller class of idiopathic hemorrhages, those that are active being allied to the active form of hyperemia, and bearing a close analogy to inflammation, both as regards the symptoms which accompany them, the description of persons in whom they principally happen, and their remarkable tendency to recur? whilst the passive belong to that condition of the body which is attended with some morbid change

in the blood; a circumstance which would of itself go far, perhaps, towards explaining their simultaneous occurrence from various organs?

However this may be, that hemorrhages are sometimes what is called active, and sometimes what is called passive, is a valuable fact, apart from all hypothesis.

And concerning these morbid effusions of blood, there are several other well-ascertained general facts, with which it imports the physician to be acquainted, but of which the limits of this work will allow of a cursory enumeration only.

In the first place, hemorrhage by exhalation, of whatever kind, takes place much more frequently and readily from some tissues of the body than from others, and most especially of all, from the mucous membranes.

Upon this important fact have arisen questions which, although not without interest in themselves, do not admit, in the present state of our knowledge, of positive solution. Has it any relation to the manner in which these membranes, and the tissues subjacent to them, are supplied with a capillary circulation? or to their laxity of attachment, which facilitates and favours the accumulation of blood therein? Again, has the density or consistence of their natural exhalations any thing to do with this disposition to hemorrhage in the mucous membranes? May we suppose that the vessels or orifices appointed to exhale mucus afford a more ready passage to the blood than those which give egress to thinner fluids—serum for example, or the cutaneous perspiration?

Hemorrhage is also liable to occur, but much more rarely, from the serous membranes; from the skin; into the cellular tissue of various parts of the body; and into the substance of the several viscera.

Another important fact in regard to these hemorrhages is, that they proceed more frequently from certain parts of the body than others, according to differences of age. Thus, in *childhood* they are most common from the membrane that lines the nasal cavities; in *youth* from the mucous membrane of the lungs and bronchi; in the *middle years* of life, and towards its decline, from the rectum, uterus, and urinary passages; and in *old age* from the bloodvessels of the brain.

There are persons (and the case is far from being an uncommon one) who are subject, during the greater part of their lives, to certain hemorrhages, which occur again and again, without any notable detriment of the general health, independently of any obvious exciting cause, and (as it would seem) from some inherent necessity of the system. Habitual hemorrhage of this kind is said to be *constitutional*: it takes place more commonly from the rectum than from any other part, although cases are recorded of its occurrence from the mucous membrane of the bladder, of the bronchi, and of the nasal cavities. Linked, in some inexplicable manner, with the original constitution of the body, this disposition to hemorrhage, as might be expected, is some-

times observed to be hereditary. It differs from ordinary hemorrhage of the active kind, by affecting, indiscriminately, those who are feeble and those who are robust, but most remarkably by its recurrence at periods more or less regular.

The celebrated Gall used strenuously to maintain the doctrine of a periodic movement in the male system analogous to that which returns monthly in the female, and marked by signs which all might observe who would take the pains to look for them. That the analogy really obtains in many points, and more distinctly in some individuals than in others, there can be no doubt. It has been incidentally noticed indeed by several writers; and Chomel has given the following clear summary of the principal features of the resemblance.

“The primary appearance of these constitutional hemorrhages is sometimes preceded by a state of general indisposition, more rarely by slight febrile disturbance, and even, according to some observers, by a sort of chlorosis analogous to that which affects young girls in whom the menstrual evacuation is delayed or suspended. The hemorrhage sometimes recurs at precisely regular intervals, and by *monthly* periods more commonly than any other; being announced, on each occasion, by the same preludes, proceeding from the same part, continuing for the same space of time, and furnishing always about the same quantity of blood. Its accidental interruption is almost uniformly the cause or the effect of some derangement of the health. It is furthermore remarkable that these habitual hemorrhages, like the catamenia, do not ordinarily occupy the whole course of life; in most individuals they do not commence before the period of adolescence or youth, and they cease altogether, or recur at distant intervals only, in declining age. When they become excessive, they also (like hemorrhage from the uterus) enter the exclusive domain of pathology.”

One of the most singular facts relating to hemorrhages is that they are, not unfrequently, vicarious or supplemental—sometimes of each other—but more often, in the female, of the menstrual discharge, between which and the constitutional hemorrhages of men there has just been shewn to be some degree of analogy. Bleedings from the bladder and from the mouth sometimes follow upon the suppression of constitutional hemorrhoids; from the lungs, stomach, or rectum, upon the suspension of the menses. These hemorrhagic deviations, as they are sometimes called, take place commonly by the same organ on each occasion, sometimes by different organs in succession. It is almost always in this supplementary manner that the rarer forms of hemorrhage occur, and those of the skin in particular.

This peculiarity in regard to hemorrhage seems calculated to throw some light upon the obscure doctrine of *revulsion*; a doctrine which, though very imperfectly understood, is of continual avail in the practice of physic.

The *symptoms* which accompany internal hemorrhage are modified by various circumstances; and the degree of certainty which they impart to the diagnosis differs much in different cases.

If the part into which the blood is directly extravasated communicates with the exterior of the body, the expulsion of some of that fluid sooner or later demonstrates the case to be one of hemorrhage. The particular symptoms will have some relation to the functions of the organ that furnishes the blood, and to the time that intervenes between its extravasation and its ultimate expulsion; and certain characters will often be derived from the parts traversed by the blood before it reaches the surface. It is even difficult sometimes to determine whether the blood proceeds from a certain organ, or from those parts that lie between it and the natural outlet by which it ultimately escapes.

The blood itself will be generally more fluid and brighter in proportion as it is effused in greater quantity, and near the surface; more in clots and darker in colour, in proportion to the length of time that it has remained within the body after its escape from its proper vessels: and this length of time may depend upon the smallness of the quantity of blood effused, and the consequent tolerance of the organs through which it may have passed; or upon the actual space traversed.

If the locus of the hemorrhage does not communicate with the external air, we are without that certainty which results from the actual spectacle of the blood. But we are then assisted by *local* signs, which spring from the pressure on, or the laceration or distention of the suffering viscus, or of the parts contiguous to it; and by *general* signs, many of which are the same whether the extravasated blood reach the exterior or not. These general signs again are modified according to several circumstances. They principally vary according to the quantity of blood poured out, and to the *rapidity* of its effusion; something also will depend upon the particular organ, and much (when the quantity is the same) upon the age and strength of the patient.

Besides the symptoms which are observable at the very time of the bleeding, there are others, of much interest, which occur more remotely. These may sometimes result from a single profuse hemorrhage, but more commonly they are owing, not so much to one large bleeding, as to a repetition of such as have scarcely any immediate perceptible influence on the system.

Some of the general symptoms,—such as paleness of the face, feebleness of the pulse, coldness of the extremities, and a tendency to syncope, which have been observed to ensue upon the eruption of the blood, have been ascribed to the alarm and sense of danger which the sight of that fluid is calculated to produce in the mind of the patient. This is probably true to a certain extent; but the ex-

planation does not apply to those cases in which the hemorrhage is strictly confined to the interior of the body, yet in which the symptoms just alluded to are often strongly marked.

For the method of treatment applicable to internal hemorrhages, the reader is referred to the several articles in which the different forms and varieties of hemorrhage are practically discussed. A very cursory notice only can here be taken of the general means which are found most effectual in restraining the actual efflux of the blood.

A preliminary question, however, of some importance, here presents itself. Is it in all cases of hemorrhage proper or safe to attempt to stop the bleeding?

Without going into detail, it may be stated as a rule that *constitutional* hemorrhages ought not to be interfered with, so long as they have no perceptible injurious influence upon the health, and proceed (as they mostly do) from parts of which the structure is not likely to be spoiled, nor the function impaired, by the passage of the blood. The most common seat of these constitutional hemorrhages is the rectum, to which the conditions just mentioned are, fortunately, both of them applicable. Epistaxis supplies a less frequent example of the same kind. When these habitual hemorrhages deviate from their usual channel, and are (as it were) transferred to some more important organ, it will generally be right, among other remedial measures, to endeavour to recal the original hemorrhage. It is very seldom that the metastasis takes place *for the better*, from a part where the bleeding is attended with danger, to one where it is comparatively harmless.

Again, it will seldom be proper to employ direct expedients for stanching the flow of blood in the small class of idiopathic and active hemorrhages, unless the quantity lost is so great as to endanger the safety of the patient. Such hemorrhages have commonly a tendency to cure themselves, by relieving the local or general plethora on which they depend.

Nor may we venture to use *direct* means for checking most of those hemorrhages which result from present inflammation.

With these exceptions, it will generally be right to arrest the effusion of blood as speedily as may be; though in some of the symptomatic hemorrhages this may even be of secondary importance.

To this end the patient is to be surrounded as much as possible with cool fresh air, and kept in a state of absolute quiet. All motion of the body, and emotion of the mind, all kinds of stimulating food or drink,—every thing in short which has a tendency to hurry the circulation, should be diligently avoided; and that position of the body should be chosen which is the least favourable to the afflux of blood towards the part affected. The horizontal posture will be proper in hemorrhage from the bowels, the uterus, or the urinary organs.

In epistaxis and in cerebral hemorrhage, the head should be raised.

Of the actual remedies used for checking the further escape of the blood, one of the most important is venesection. The objects of artificial bloodletting are, to diminish the force of the heart and arteries, to lessen general plethora, to remove local congestion, and to divert the current of the blood from the suffering organ. The method, and the amount, and the repetition of the bloodletting must of course be regulated by the circumstances of each particular case. The same objects may sometimes be effected by other modes of general depletion, and especially by the use of purgative medicines.

Next to bloodletting, astringents constitute the great resource against hemorrhage; and of these *cold* is one of the chief. It may be placed in direct contact with the bleeding surface, as when ice is swallowed to restrain hematemesis; or cold water injected into the rectum in hemorrhoids, or into the vagina in flooding from the uterus; or it may be applied to the surface of the body, as near as possible to the seat of the hemorrhage, as to the nose and forehead in epistaxis; to the epigastrium in hemorrhage from the stomach; to the lower part of the abdomen, or to the perineum, in hemorrhages from the intestines, uterus, or urinary organs. But the influence of cold in constringing the smaller vessels is not confined to the part with which it is in contact: it will stop hemorrhage by the sympathetic shrinking which it produces in distant parts. Epistaxis, for example, has often been arrested by the sudden apposition of cold water to the neck, back, or genital organs. Of its even mischievous power in this way we have continual illustration in the suppression of the catamenia by cold applied to the feet.

There is a long catalogue of medicinal substances, which are esteemed to possess more or less of a specific virtue, when taken internally, in arresting the flow of blood. Most of these are of an astringent nature, and some of them are essentially useful. The binacetate of lead enjoys in this country a higher character perhaps than any other of these substances.

Many vegetable matters, and some artificial compounds, frequently employed in internal hemorrhages, seem to owe their astringent and styptic properties to the gallic acid which enters into their composition. Such are the rhatany root, uva ursi, bistort, tormentil, the pomegranate, kino, catechu, the several preparations of gall-nuts, and the nostrum called Ruspini's styptic.

The power of arresting internal hemorrhage has also been confidently ascribed by different persons to nitre given in large doses, to the mineral acids, to the muriated tincture of iron, to alum, to the oil of turpentine, to the secale cornutum, and to various other substances; a more particular account of which may be found in other parts of this work,

under the head of the individual hemorrhages.

HEPATITIS.—See LIVER, INFLAMMATION OF.

HEREDITARY TRANSMISSION OF DISEASE.—The cases are rare in which a disease under which the patient labours displays itself in the offspring at birth, or so recently after it, that it can be supposed to be directly transmitted. Small-pox and syphilis are the diseases most frequently referred to as furnishing examples of direct transmission. Small-pox has been discovered in infants at birth, as was proved by Mr. John Hunter, and instances of marks of this disease on still-born infants are not infrequent; but those who attend scrupulously to the niceties of language consider these as examples rather of communication by contagion than of transmission by inheritance. The same distinction, if not in any case over refined, may be drawn in cases of the communication of infantile syphilis; but as a good deal of controversy has arisen on this especial case of hereditary reception, we shall bestow a few remarks upon it.

Until the period when Mr. Hunter endeavoured to give greater precision to our ideas respecting lues, many diseases, particularly scrofula, were ascribed to a syphilitic taint. This opinion was certainly too vague, and was adopted on very insufficient evidence, or rather on no evidence at all. Since the period mentioned, there has existed an unwillingness to admit the possibility of the communication of this disease to the fœtus in utero; and the nature of any indications of it which appear soon after birth is either questioned, or the disease is supposed to have been communicated by direct contagion from ulcers existing in the genitals of the mother. Many persons have questioned the validity of these objections, and among others the late Mr. Hey of Leeds, whose accuracy will not be doubted. This gentleman relates cases of infantile syphilis which could not have occurred in the manner adverted to, the disease never having existed in the genitals of the mother, but having been communicated to the nipples whilst the breasts were drawn in a previous confinement by a person habitually employed in this way, and who had contracted it by the mouth in performing the same operation on an infected female.* The writer can add his experience to that of Mr. Hey on this point, having seen many cases of what appeared to be infantile syphilis occurring speedily after birth, though at the time of delivery the mother was entirely exempt from ulcers of the pudenda. If the identity of the disease is questioned, it may be urged that the eruption is of the characteristic copper colour, the throat is very generally affected, in some cases ulceration of the genitals exists; in short that it has all the sym-

* Medico-Chirurgical Transactions, vol. vii. part ii.

ptoms of syphilis, and is speedily remediable by mercury. A singular circumstance connected with these cases is, that they occasionally occur in infants whose parents do not labour under manifest symptoms of the disease, either at the time of generation or during pregnancy; but they are never observed in the offspring of those who have not, either one or both, more commonly both, previously laboured under it.

These two diseases, and tubercles, which have been discovered in the lungs of still-born infants, furnish perhaps the only examples of direct hereditary transmission. Other diseases, for instance deafness and blindness, are connate, and are frequently observed to occur in members of the same family; but these individuals will generally be found to have sprung from parents who did not labour under the same privation. It is true that persons born deaf or blind rarely marry, so that much opportunity is not afforded of observing how far this family peculiarity, however acquired, is transmissible; but the same fact may be adduced as an argument that it is not received by inheritance. Of one hundred and forty-eight scholars at one time on the foundation of the Deaf and Dumb Institution in London, one was of a family in which there were five deaf and dumb; one in which there were four; eleven in which there were three; and nineteen in which there were two. Of the scholars, fifty-seven were girls, and the rest boys; and none of them were the children of deaf and dumb parents. The gentleman who superintended the manufactories, and who consequently had the best opportunity of tracing the subsequent history of his scholars, stated that some of them were married and had children, all of whom were perfect in the organ of hearing. One instance occurred in which both parents had been born deaf, yet the children possessed the faculty of hearing.*

Cataract is frequently observed as a congenital disease in members of the same family; but in this case it is found not to appear in successive generations as if it were at once connate and hereditary. Hydrocephalus, too, is connate, and members of the same family are born with it; but being in the adult a rapidly fatal disease, it cannot of course be received by inheritance.

Though nature is thus sparing of the direct transmission of disease from parents to offspring, she is not equally so of morbid tendencies; and what are commonly called hereditary diseases are so merely by predisposition. That children inherit the outward bodily configuration and manifest peculiarities of one or other of their parents, is well known; and that they likewise derive from them that more hidden weakness of certain organs by which these are prone to take on diseased action, is proved by the experience of ages. The hereditary predisposition to scrofula, consumption, gout, and in-

sanity, is so essentially a part of the medical creed, that a professional man called to a case supposed to belong to any of these disorders immediately endeavours to strengthen his diagnosis by information gathered from the family history. But besides these very common examples, various other diseases, such as asthma, angina pectoris, a general hemorrhagic disposition, apoplexy, epilepsy, and various nervous disorders, blindness and deafness, not congenital, and, according to Dr. Adams, elephantiasis, are transmitted in predisposition from generation to generation. To this sufficiently formidable list, some persons are disposed to add goitre and cretinism, though this can be regarded as a mere speculative opinion; but an affection closely allied to the latter, idiocy, is unquestionably hereditary. Of this Haller presents us striking examples in two noble families, into which it had been introduced above a century before the time he wrote, and where it was still manifesting itself in some individuals of the fourth and fifth generations. Certain idiosyncrasies too, which, like idiocy, cannot be regarded as diseases, are observable in successive generations of the same family; for instance, a peculiar susceptibility to the effect of certain remedies, such as mercury and opium.

Of transmissible diseases, some have appeared in several individuals at a certain period of life, and such members of the family as have escaped at this critical period have remained exempt from the affection. All the members of the family of the *Le Comptes* saw clearly till about the age of sixteen or eighteen; at that age some of them, without any apparent cause, became dim-sighted, and grew gradually more so till total blindness ensued: such has been the case for three generations with a certain number in each race; but such as have escaped at that critical age have retained their sight through life.* In the family of Mr. Bass, at Peterborough, deafness has observed a similar course.† Hydrocephalus, the disposition to which exists in certain families, though it cannot be regarded as an hereditary disease, has often attacked individuals of the same race at the same age; and those who have then escaped have continued free from the complaint. The same observation has been made of elephantiasis, angina pectoris, and other diseases.

Like other family peculiarities, hereditary predisposition to disease may cease in one generation to appear in a subsequent one; or, though manifesting itself in each generation, it may pass to the subsequent one through an individual who has escaped it. Of this mode of transmission an extraordinary example occurs in the relation of cases of hereditary hemorrhage by Dr. Riecken.‡ These cases occurred in the principality of Birkenfeld in Oldenburg.

* A Treatise on the supposed hereditary properties of Diseases, by Joseph Adams, M.D. &c. p. 66.

‡ Medicinische-Chirurgische Zeitung, Nov. 1830, and Edinburgh Med. and Surg. Journal, No. 108.

The parents had never been subject to hemorrhage, and the father, Ernest P., was living in good health in his eighty-sixth year at the time of the publication of the narrative. The couple had twelve children, five sons and seven daughters, of whom three boys and one girl died of hemorrhage. Their youngest daughter, who never suffered from the disease, married a stout healthy man and had six children, four boys and two girls, of whom three boys died of hemorrhage. There is no trace of any member of the family, either on the male or female side, anterior to the children of Ernest P., being affected with the disease.

How the hemorrhagic disposition arose in the second generation of Ernest P.'s family we know not; but in certain cases the first appearance of an hereditary disease in an individual can be traced to an assignable cause. The natives of the warmer regions of the earth become affected in the colder latitudes with scrofula and consumption; and the latter disease manifests itself under such circumstances even in inferior animals, as in the monkey tribe. Certain modes of living engender gout; and elephantiasis appears to be produced by a peculiar climatorial influence.

It has never been observed that these diseases, when introduced by manifest causes, have not partaken of the property of transmission to succeeding generations. If they do indeed possess this property, (and there seems no reason at present to doubt it,) nature would appear to have instituted laws for the transmission of disease on two points, the opposite of those established regarding hereditary varieties in manifest structure. The laws in the latter case are, as illustrated in Dr. Prichard's very elaborate and ingenious work, that connate varieties are apt to appear in the progeny; but that changes produced by external causes terminate with the individual, and have no influence on his descendants.* It will have been remarked that congenital blindness and deafness, though family diseases, or apt to prevail in members of the same generation of the same family, are rarely if ever hereditary. Dr. Adams suggests that though congenital peculiarities and redundancies are hereditary, connate privations are not so, and that deafness and blindness belong to the latter class; and in this way, provided it is ascertained that connate privations do not descend to offspring, the discrepancy in the law may be reconciled. Dr. Prichard endeavours to adjust the other difference by supposing that the exciting causes of diseases act upon an existing predisposition laid by nature in the original stamina and habit of the body, and that the occurrence of a malady from their application is no proof that it is engendered by them, but that they are the mere occasion on which a congenital weakness previously hidden is rendered manifest. This view he illustrates by the example of gout; but were other instances chosen, such as those of scrofula and

consumption occurring in the natives of warm when removed to cold climates, it appears questionable whether the doctrine would be found to apply invariably; whether it would not rather be proved that a morbid peculiarity may be strictly engendered by an external cause, and being thus engendered, may be transmissible to posterity. Perhaps, too, the rule that acquired peculiarities in general are not hereditary is laid down too absolutely. The writer has in many instances observed in the case of individuals whose complexion and general appearance has been modified by residence in hot climates, that children born to them subsequently to such residence have resembled them rather in their acquired than primary mien.

It is natural to enquire whether we derive any useful inference from our knowledge of the hereditary property of certain diseases? The most important and practical inference that can be deduced is, that the descendants of those who labour under any hereditary disease should be shielded as far as possible from its exciting causes; for the predisposition is of various degrees, in some so intense that at a certain period the disease occurs by the spontaneous act of the constitution; but in others so slight, that the cooperation of noxious agents is required to render it manifest. Hence the descendants of the gouty should observe the most rigid temperance; certain climates should be selected, if possible, till a certain period of life, for those of the consumptive; the offspring of the maniacal should be guarded as much as possible from mental irritation, and from all habits of life calculated to call their inherent tendency into action; whilst a nutritious and invigorating regimen and warmth should be appropriated to those who, there is reason to think, have derived the scrofulous diathesis from their ancestors. Another practical inference which might be deduced is, the propriety of avoiding matrimonial alliances between families possessing the same hereditary taint; and, generally, of forbidding all such alliances between kindred families, for few are perhaps free from some congenital weakness or susceptibility, and, to use the phrase of the cattle-breeders, all predispositions to disease are rendered more intense in families by breeding *in and in*.

(Joseph Brown.)

HERPES, from the Greek *ἑρπεν*, to creep. *Syn.* Cytisma herpes (*Young*); Lepidosis herpes (*Good*); Neshr (*Arabic*); Zittermahl; die Flechte (*German*); Dartre (*French*); Vesicular tetter.

Herpes is an inflammatory disease of the skin, terminating in the discharge of a quantity of thin fluid sufficient to elevate the cuticle into small irregular vesicles, which appear in groups or circumscribed patches of various forms, on an inflamed base, the skin in the intervals retaining its healthy aspect. The disease, which is non-contagious, generally passes through a regular course "of increase, maturation, and decline, and terminates in

* Researches into the Physical History of Man. 2d edition, vol. ii. p. 536, et seq.

about ten, twelve, or fourteen days.* Biett and Rayer assert that it is rarely preceded by fever, and unless when it proves critical of some other disease, that it cannot be referred to any appreciable cause. Our own experience, however, accords with that of Bateman, that it is frequently preceded by considerable constitutional disorder. At first the vesicles are filled with a colourless pellucid fluid, which gradually becomes opaque and of a yellowish hue, but not purulent; after which it forms crusts, which drop off, except when ulceration occurs. The eruption is attended with tingling; sometimes with lancinating pains, as if hot needles were run into the part. In some of the forms of the disease, as the vesicles concrete and the crusts fall off in one part, fresh patches arise in the immediate vicinity, and thus the disease creeps over a considerable portion of the skin.

Herpes is distinguished from pompholyx by the vesicles appearing in groups or patches on an inflamed base; and from erysipelas, by the vesicles not being preceded by redness and tumefaction; by their distinct yet clustered character, and the state of the skin between the clusters. It is scarcely possible to confound it with eczema or impetigo, neither of which assume the purely vesicular form, nor run the same regular progress within a limited period; and both of which form thin plates or semi-pellucid crusts, from under which a thin acid fluid exudes, instead of the dry harsh scab which characterises herpes.

In Bateman's synopsis we find the various appearances of herpes constituting six distinct species; and in this view of the subject he is followed by Rayer.† Biett, on the contrary, considers every form of herpes a variety of one species, *phlyctenodes*, differing only in the seat of the eruption, or in the figure of the clusters of vesicles. Thus he regards herpes *labialis* and herpes *præputialis* as varieties of herpes *phlyctenodes*, distinguished from it only by having a determined site; while herpes *zoster*, herpes *circinnatus*, and herpes *iris*, are regarded equally as varieties, differing merely in the form of the vesicular patches. In the view which an extensive experience has led us to take of the generic disease, we feel authorized in dividing it into two distinct species, herpes *phlyctenodes* and herpes *iris*, the characteristics of which are well defined: all the other forms, generally regarded as species, will be found to be mere varieties of herpes *phlyctenodes*, however they may differ in the figure of the clusters, or in the parts on which they appear: indeed the modifications which both herpes *labialis* and herpes *præputialis* display depend on circumstances connected altogether with the parts on which they appear. Taking this view of the general disease, we are of opinion that all its forms are comprehended in the following arrangement:—

Species 1. *H. phlyctenodes*.

Var. a. *H. zoster*.

— b. *H. circinnatus*.

— c. *H. labialis*.

— d. *H. præputialis*.

— 2. *H. iris*.

Species 1. HERPES PHLYCTENODES.—This species appears in irregular agglomerated groups of small, transparent, globular vesicles, not larger than a millet-seed. It is usually preceded by one or more slight febrile attacks, accompanied by thirst, heat of stomach, and flatulence, which are not immediately relieved by the appearance of the eruption, but on the contrary are sometimes aggravated by the heat and tingling in the patches of vesicles as they continue successively to appear. The clusters rise in various parts of the body; the cheeks, the forehead, the neck, the trunk, and the extremities being indiscriminately the seat of the eruption. The vesicles differ greatly in size, but the smaller are comparatively the most numerous; and when the disease spreads extensively, the clusters are chiefly made up of small vesicles.

On the spot where each cluster appears, a sensation of heat and tingling is felt; at which time, says Biett, minute red points may be detected, very closely grouped, and over these on the following day the vesicles display themselves on an inflamed base, resisting compression, and varying in size, from that of a small millet-seed to that of a pea. We have never observed the previous state here described, although its existence is highly probable: in general we have seen the spots, which afterwards became groups of vesicles, appearing as simple red blotches, which feel rough when the finger is passed over them. Rayer states that the number of vesicles in each group varies from twelve to fifteen or more.* Several of these groups rise together, forming clusters, in which the intervening skin retains its natural colour; although within, and for a small space beyond each group, it is red. The fluid in the vesicles is at first generally colourless, but occasionally of a brownish hue; it gradually thickens, probably owing to the absorption of the watery part, and in ten or twelve hours acquires opacity and looks milky or pus-like; sometimes in the larger vesicles it appears bloody. About the fourth day the larger vesicles break and discharge their fluid; the inflamed surface acquires a dull purple hue; and while many of the smaller vesicles flatten and disappear, the larger dry and change into irregular yellow or brownish crusts, which fall off about the eighth or tenth day, although sometimes not until the fifteenth or twentieth. The skin for a considerable time retains a reddish hue, indicating the seat of the previous eruption. In this manner the successive clusters run their course.

Authors agree that the causes of herpes *phlyctenodes* are very obscure. In almost every instance which we have seen, the imme-

* Bateman's Practical Synopsis, 7th edit. p. 319.

† Traité Théorique et Pratique des Maladies de la Peau, tome i. p. 226.

* Op. cit. p. 227.

diate or exciting cause appears to be derangement of the digestive organs, accompanied by a highly irritable state of the system. It has appeared also occasionally to proceed from catarrhal or other inflammatory febrile affections, in which the eruption may be regarded as a translation of diseased action from the mucous membrane to the skin.

The continental writers have laboured to mark the symptoms which distinguish herpes *phlyctænodes* from pemphigus. In our opinion it is scarcely possible to confound them; in the one the eruption consists of distinct solitary bullæ, in the other of clusters of vesicles upon isolated surfaces.

With respect to the treatment of herpes *phlyctænodes*, as this differs little from that which is requisite in the varieties, the notice of it may be deferred until these shall have been described.

Var. *a. Herpes zoster (shingles)* differs from herpes *phlyctænodes* chiefly in the size of the vesicles forming the groups, in the seat of the disease, and the manner in which the clusters successively appear and extend over the body. The vesicles, however closely agglomerated, are from the first distinct: they generally enlarge in twenty-four hours to the size of pearls; are perfectly transparent and filled with a limpid fluid: the inflamed base of the pustules, which are considerably larger and more irregular than those of herpes *phlyctænodes*, extends some distance beyond the vesicles. The most frequent seat of this variety is the trunk of the body, and as the patches of vesicles successively appear, they extend either round the waist in an oblique direction like a sword belt, or across the shoulders, or from the shoulder they extend to the arms, or from the nates down the thighs, in an oblique direction to the knee. A perpendicular position of the clusters is very rare: Rayer mentions having seen it on the thigh: he also describes a case in which it extended from the face into the mouth. "La moitié gauche de la langue est tuméfiée, épaisse, rouge, et couverte de plaques blanches, molles, irrégulières. Les unes ont les volumes des vésicules de la peau, les autres se rapprochent des bulles par leur grande dimension. L'épaisseur de ces plaques est égale à celle d'une feuille de papier, &c. La salive, secrétée en abondance, est filante; l'haléine est fétide, mais n'a point l'odeur particulière qui s'exhale de la bouche chez les personnes qui ont abusé des préparations mercurielles."* The most frequent seat of the clusters is the lower part of the thorax: the right side is more frequently attacked than the left: the eruption never appears on both sides at the same time.

Rayer has placed this variety among the bullæ, although he regards it as holding an intermediate place between bullæ and vesicular inflammation.† The eruption of shingles ap-

pears to be an affection solely of the reticular web of the cuticle, and never extends, like erysipelas, to the subcutaneous cellular tissue.

The premonitory symptoms in shingles are languor, loss of appetite, febrile rigors, headache, a quickened but small pulse, sometimes sickness, pains darting across the chest and epigastrium, and a sensation of scalding heat or deep-seated pain in the spot where the first patches of eruption are likely to appear. In old persons, and in those of delicate habits, this feeling of local heat and pain often continues for a week or more previous to the appearance of the eruption, by the coming out of which it is almost instantly relieved. It is sometimes so severe, that it has been mistaken for pleurisy, and treated by venesection and other depletory means. At other times the precursory fever is so slight, that the first notice which the patient receives of the presence of the disease is a sensation of heat and tingling on some part of the trunk, where he finds on examination patches of shining, pearly, or silvery vesicles already formed. Sometimes the patches appear at the opposite extremities of the zone, and join by the successive patches extending towards the centre. The vesicles in the separate clusters attain their greatest size, which seldom exceeds that of a pea, in three or four days; and at this time the inflammation of the base of the patch is at its height, of a vivid redness, becoming fainter as it extends beyond the limits of the cluster of vesicles. Generally before the fourth day, while the new clusters begin to appear, the lymph in the first set of vesicles becomes opaque, acquires a milky or yellowish hue, and approaches in some instances almost to the state of pus. The inflammation of the base now changes to a bluish or livid hue, and the vesicles flatten or subside: some, however, break, and either spontaneously or from friction, discharge their fluid, which concretes in dark-coloured scabs. These crusts harden and adhere firmly for ten or twelve days and then fall off, leaving the skin red and tender; and when the vesicles have been rubbed and become ulcerated, cicatrices or pits sometimes remain. These symptoms vary according to circumstances; thus in old people, or those enfeebled by want, the vesicles enlarge almost into bullæ, break soon, and almost always ulcerate; and even, according to Bielt, occasionally have been followed by gangrene. Yet the same physician has never seen the disease attended with much fever or general derangement of the system.

The febrile symptoms which we have observed, generally subsided when the eruption was complete, but not always; and we have seen cases in which the uncomfortable feelings seemed rather augmented than diminished during the whole progress of the eruption; and more especially the deep-seated pain described by Bateman, which, he says, "continues to the latter stages of the disease, and is not easily allayed by anodynes."

Shingles is not a contagious disease, and may occur several times in the same individual. In the greater number of instances it appears

* Traité des Maladies de la Peau, tome i. p. 230.

† Cette maladie forme réellement l'anneau intermédiaire entre les inflammations bulleuses et les inflammations vésiculeuses. Tome i. p. 202.

towards the termination of some acute disease. It occurs most frequently in persons between twelve and twenty-five years of age, although occasionally the aged suffer severely from it. Those who have a delicate and irritable skin are most liable to its attacks. It prevails more in summer and autumn than in spring and winter.

It is scarcely possible to mistake shingles for any other vesicular disease, unless in its early stage, when it resembles in some degree herpes *phlyctanodes*; but it may be distinguished by the appearance of the red patches on which new clusters of vesicles are about to appear. The absence of swelling of the skin, and of the disappearance of redness on pressure, readily distinguish it from erysipelas.

The general treatment of shingles is the same as that of the other varieties of herpes *phlyctanodes*, and therefore need not be detailed here. With respect to local applications, a gently stimulant spirituous lotion to the inflamed clusters, to which a portion of tincture of opium may be added when the pain and irritation are severe, may be employed. By these means the vesicles are prevented from breaking; but when this occurs, nothing is so serviceable as the oxide of zinc ointment.

Var. *b. Herpes circinnatus. Ringworm.*—This variety of herpes *phlyctanodes* is of very frequent occurrence; and being unaccompanied with any constitutional affection, is of little moment. The vesicles are small, and form in a circle, inclosing a portion of the skin seemingly unaffected, while a red inflammatory blush extends to some distance around the cuticle of the circle of vesicles. The fluid contained in the vesicles is generally discharged in a few days; after which dark prominent crusts congregate over them; and at this time the centre, which seemed free from disease, becomes rough and exfoliates.

The eruption of the vesicles is preceded by a red spot of various sizes, from half an inch to two inches in diameter: it is generally circular, but occasionally oval. In a very short time after the redness appears, the vesicles, minute and globular, can be traced by the aid of a glass, filled with a transparent fluid, which becomes opaque before they burst. Sometimes the fluid is absorbed; in which case the vesicles shrink and exfoliate almost imperceptibly. The period in which each circle runs its course is from eight to ten days; but the circles appear in succession, and as each requires a period of eight or ten days to be perfected and desquamate, the disease is thus protracted to two or three weeks or longer. When the crusts fall off, they leave a redness which remains for some time; but no other inconvenience attends the eruption. In some instances, instead of the regular circle, the whole central spot is covered with minute vesicles, which enlarge sometimes to a considerable size, and are accompanied with much heat, pain, and irritation. When this form of disease occurs, the clusters rapidly spread and pass over the great part of the arms, the places on which this variety generally shews

itself. The feverish state does not at once abate after the eruption appears: it continues to increase for five or six days; and about the ninth day the vesicles break, and the fever suddenly ceases.

The vesicular circles most commonly appear on the arms, the shoulders, the chest, the neck, and the face; and in young girls of a delicate frame of body, with a thin and irritable skin, the circles frequently display themselves on the chin.

The disease is very frequent among children, and is commonly but erroneously supposed to be contagious. Its exciting causes are obscure; and it is ushered in merely by a sensation of slight tingling and itching.

This variety of herpes, if it appear on the forehead and at the roots of the hair, may be mistaken for porrigo *scutulata*; but the vesicular character of the eruption, the regular course which it runs, and the hair not falling off, very easily enable us to distinguish it from the contagious ringworm of the scalp, as porrigo *scutulata* is termed.

No internal treatment is required: lotions containing either of the mineral alkalies, or sulphate of zinc, or alum, may be applied with advantage. Black writing-ink is a domestic application which has proved as beneficial as any that has been suggested.

Var. *c. Herpes labialis. Herpes of the lips.*—This variety differs only in the situation which it occupies. It sometimes extends round the whole mouth, sometimes its seat is the upper, sometimes only the lower lip. When it does not surround the mouth, it is not unusually confined to the angles: wherever it appears it rarely attacks the true lips, but frequently impinges upon the line of union between these and the skin, and at the same time patches of the eruption rise on the cheeks and alæ of the nose. The vesicles, like those of the other varieties, at first contain a transparent lymph, which in twenty-four hours assumes a purulent aspect, and in three or four days becomes more yellow than that usually found in pustules, few crusts forming. The lips, as the disease advances, swell, become hard, sore, stiff, and painful, with a sensation of great heat in the affected parts. After the crusts fall, the surface remains red, harsh, and painful; cracking every time the patient laughs or opens the mouth wider than usual.

Herpes labialis is more decidedly the sequel of a distinct febrile state of the system than any of the other varieties. This febrile state is often of a catarrhal kind, and not unfrequently results from sudden alternations of heat and cold, particularly sudden exposure to damp cold air, after having been confined in a hot or crowded room. The febrile affection is manifested by rigors, headach, pains in the limbs, anorexia, lassitude, and languor. This variety of herpes is often a critical eruption, appearing on the decline of acute diseases, which rapidly disappear as soon as the vesicles, or the inflamed bases on which they rise, shew themselves. Severe catarrhs often terminate in this manner; and the appearance of this vesicular disease is

considered a favourable symptom in affections of the bowels, and in the latter stages of remittent and low malignant fevers. It occasionally becomes chronic.

In general this variety requires no particular treatment; successive crops of the eruption rarely appearing, so that it runs its course in three or four days, and spontaneously disappears. To allay the heat and itching, diluted alcohol or a solution of zinc proves serviceable. When it becomes chronic, (and in this state it is almost always symptomatic of some deranged state of the digestive organs,) the hydrargyrum cum creta, combined with James's powder in the proportion of ten grains of the former and four of the latter, may be administered every night at bed-time; and during the day the liquor potassæ, in full doses, taken in the decoction of the root of the *rumex acutus* or *obtusifolius*, rarely fails in affording relief. The decoction should be made at first with not more than an ounce of the sliced root to a quart of water, and reduced by boiling to a third; but if the disease do not soon yield, double this strength will be required. The diet should be light, and consist chiefly of milk and farinaceous matters. The diluted ointment of nitrate of mercury is the best topical application in this chronic form of herpes labialis.

Var. d. Herpes præputialis. Herpes of the prepuce.—Although this variety of herpes is not uncommon, yet until Dr. Willan pointed it out as an herpetic eruption, and Bateman accurately described it, it was often confounded with syphilis and treated as such. It more nearly resembles the last variety, herpes labialis, than any of the others. It appears on both the external and internal surface of the prepuce, and not unfrequently on the glans penis. The eruption of vesicles is preceded by a teasing itching and tingling in the prepuce, which appears slightly swollen and inflamed, and covered with two or three red patches, on which, when closely examined, minute vesicles may be observed rising nearly in a circle. These rapidly increase in size; the lymph loses its transparency and assumes a milky hue; and in another day they are coherent and almost pustular. If the vesicles be not disturbed, they sometimes do not break, but the lymph is absorbed, and the shrunk vesicles desquamate; but at other times they break, and form ulcers covered with a whitish fur, and having an elevated base, not unlike the aspect which chancre assumes; and when they are rubbed, or improperly managed by caustic or acrid applications, a tedious state of ulceration sometimes supervenes. When the vesicular patches are situated on the internal surface of the prepuce and on the glans penis, the inflammation is more severe than when the exterior of the organ is the seat of the disease. In some instances the itching and tingling which accompany the eruption are so severe as to prevent sleep. On the exterior, the vesicles terminate about the fifth or sixth day, forming small, hard, acuminate scabs, under which the healing process is carried on; and about the ninth or tenth day the scabs fall and leave

the surface slightly indented. In many instances the disease does not run this regular course, but yields to very simple means in forty-eight hours.

This variety of herpes is rarely observed in young men; on the contrary, persons in the decline of life are most subject to it, and it not unfrequently accompanies stricture of the urethra, or an irritable state of this canal. It is also sometimes produced by an acrid state of the secretion at the root of the glans; and we have seen its approach checked by keeping the part between the glans and the prepuce clean with soap and hot water, and afterwards introducing a small piece of clean dry lint to absorb the acrid fluid. Dr. Bateman properly rejects the idea of Mr. Pearson, that it is caused by mercury. The most severe case of the disease which we have seen occurred in a gentleman who had never taken mercury. We cannot, however, agree with the opinion that it is altogether independent of stricture, or at least of irritable urethra: we think that we have also observed it sympathizing with derangements of the chylopoietic viscera. It is more liable to recur than any of the other forms of herpes.

As all these different descriptions of herpetic eruptions are mere varieties of one genus, the general treatment required is nearly the same in all; and this is regulated chiefly by the nature and degree of the fever which precedes and accompanies the eruption. This is seldom so severe as to require the use of the lancet, unless the patient labours under some acute disease of which the herpetic affection may be regarded as symptomatic. More frequently herpes about the mouth and occasionally on the ears occurs as a salutary crisis of fevers, and ought not to be interfered with. If the digestive organs be much deranged, and the eruption can be traced to that source, an emetic will prove useful in clearing away the superabounding acid which generally prevails, and is undoubtedly one cause of the irritation of the intestinal membrane with which the skin sympathizes.

No class of medicines so effectually fulfil the indication to be answered in herpes as mild purgatives, especially those containing magnesia, as they carry off a large portion of the existing acid, whilst the magnesia allays the morbid irritability of the gastric surface. Neither calomel nor any of the very active cathartics are in general required. Diaphoretics are not indicated; and even when much heat of skin exists, more advantage is derived from the free use of diluents than from antimonials or any medicines of that class.

One of the most distressing symptoms in severe cases of shingles is the deep-seated pain which often occurs about the thorax, and when the pulse is at the same time quick and hard, it has, as already stated, led to the supposition that pleurisy is present. The lancet brings no relief in this case; but much comfort is afforded, and sleep secured, by a combination of colchicum, magnesia, and an opiate. The

following form is that which we have found most serviceable :

R Magnesiæ ʒi.
Vini colchici seminum m xlviij.
Tincturæ opii m xxx.
Misturæ camphoræ fʒxi. M.

Sit haustus horā somni sumendus.

In the chronic state of herpes *labialis* the treatment we have already described is commonly successful; but when the disease is obstinate, it is necessary to place the patient under a course of hydrargyrum cum creta, with decoction of sarsaparilla or of elm bark. Upon the whole, although we cannot refuse to accord with the opinions of most writers on affections of the skin, that herpes requires less of the medici diligentia than almost any other of the numerous list of cutaneous eruptions, yet the young practitioner will feel frequent disappointments if he expects all cases of herpes to run so favourable a course. It is only when they are critical of some acute disease that he may altogether disregard them: on the contrary he will sometimes find the most acute suffering precede the eruption, and a degree of general derangement of the system often so obscure as to complicate and restrain the efforts of the physician. In such cases the first object is to gain an accurate knowledge of the state of the stomach and bowels, that of the liver and the chest; and if the nervous system, which is often the case, be involved in the general derangement, to ascertain how far this depends on mental causes, as many cases of herpes, in all its varieties, may be clearly traced to grief, anxiety, and other mental sources.

Species 2. HERPES IRIS.—This species differs materially in all its characteristics from the former. It was first announced as a herpetic affection by Dr. Willan, and afterwards accurately described by Bateman. Its usual seat is on the back of the hands; but it has appeared on all parts of the body; most commonly, however, where there is little fleshy substance. It first displays itself in small red spots, which, as they change colour, are surrounded by fresh circles of inflammation, which become vesicular. The patches gradually extend until they attain the size of a shilling, the circumference assuming a radiated or star-like appearance. In the description of Bateman we are told that the first circle, surrounding the central vesicle which is yellowish, “is of a dark or brownish red colour; the second is nearly of the same colour as the centre; the third, which is narrower than the rest, is of a dark red colour; the fourth and outer ring, or areola, does not appear until the seventh, eighth, or ninth day, and is of a light red hue, which is gradually lost in the ordinary colour of the skin.”* The variously coloured rings so well defined in this description are, however, rarely observed.

This species of herpes most frequently appears in children and fair women; but neither the predisposing nor the exciting causes are very obvious. Like some of the varieties of

herpes *phlyctænodes*, it has occasionally occurred as a critical eruption. In some individuals, according to Bateman, it has recurred several times, “occupying the same parts, and going through its course in the same periods of time.”

It is scarcely possible to confound herpes *iris* with any other disease. There is one species of roseola which extends in successive circles, but it wants the vesicles, which are sufficient to characterize the herpetic disease.

With regard to the treatment of this species of herpes little requires to be said: no internal medicines are required; nor do we know any local applications likely to prove serviceable in shortening the disease. The warm bath employed only for twenty minutes, and exercise taken immediately after it, has appeared to be useful. Rayer recommends decoctions of linseed to be employed as fomentations: we have had no experience of their use, so that we are not authorised to give an opinion on the subject. Moderate bloodletting, gentle aperient medicines, and a combination of the solution of arsenic and of pure potassa, with the decoction of the *rumex obtusifolius*, have been productive of more benefit than any other means which we have employed. A small piece of soap-plaster laid over the parts affected, has occasionally been productive of much benefit.

(A. T. Thomson.)

HICCUP.—Hiccup or hickup, sometimes written hiccough, apparently from a mistaken notion of the etymology of the word. It may have been immediately derived to us from the Danish; but its origin in that as well as in some other languages was most probably an attempt to imitate the peculiar sound which it denotes. It corresponds with the French *hoquet*, and the German *schlucken*; but the Greek *λῆξις* or *λῆγμῆς*, and the Latin *singultus*, though applied to this affection, seem also to have designated the somewhat analogous one which we call *sobbing*.

The phenomena of hiccup, as observed by a by-stander, may be described to consist in a sudden, rapid, and brief inspiration (such as may properly be called convulsive), instantly followed by expiration: each of these movements being accompanied by a noise not heard in common respiration, and these noises following each other in quick succession, produce that peculiar dissyllabic sound by which the affection is characterized. The convulsive movements return at short intervals, commonly varying from half a minute to a minute, but sometimes of longer duration, and are attended by an uneasy sensation at the præcordia, which, when the hiccup is violent and often repeated, amounts even to pain.

Such are the phenomena presented by this affection, apart from any attempt to explain its *mechanism*. What this is has been the subject of much conjecture. The oldest opinion seems to have been that it consisted in a convulsive movement of the stomach; an opinion which,

* Bateman's Synopsis, p. 340.

in the then very imperfect state of physiology, was not an unnatural inference from the well-known fact that the exciting cause is commonly some impression directly made upon that organ. Since, however, the functions of the stomach and neighbouring parts have been more accurately investigated, most authors have concurred in referring the motions which constitute hiccup chiefly to the muscles employed in respiration, and particularly to the diaphragm. That causes acting upon the stomach are adequate to excite these muscles to violent and irregular contractions is familiarly known. Fits of coughing (especially in the whooping-cough) and of spasmodic asthma are often produced in this way; and whatever difference of opinion may still exist as to the particular combination of muscular actions by which vomiting is effected, it can scarcely be doubtful, especially since the experiments of Majendie, that the expulsion of the contents of the stomach is ordinarily in great measure produced by the agency of some of the respiratory muscles. If, however, two phenomena, so widely differing in their results as vomiting and hiccup, are referred chiefly to the same mechanical powers, some other cause of their difference must exist. It is probably owing to an inverted action of the muscular fibres of the stomach and gullet co-operating with the other agents in the former, and not in the latter, that the rejection of the contents of the stomach takes place in the one, but does not happen in the other.

The modern opinion, which ascribes hiccup chiefly to the respiratory muscles, rests upon the following among other arguments.—1. The phenomena of the affection, as above described, appear to consist chiefly in a convulsive act of respiration. 2. The researches of physiologists have clearly shewn that the muscles in question, or at least some of them, are capable of movements corresponding with those of hiccup in rapidity and violence. 3. We are without any satisfactory evidence that such motions are ever performed by the muscular fibres of the stomach. 4. A consideration of two popular methods of preventing the recurrence of hiccup, namely, holding in the breath for a considerable time, and making a protracted deglutition by sipping liquids; both of which seem to owe their efficacy to the power of the will over the respiratory muscles.

Some writers, while they admit the agency of the diaphragm in producing hiccup, have supposed the œsophagus to co-operate with it. Thus Mahon (*Encyclopédie Méthodique*) explains the affection as consisting in “a convulsive movement of the œsophagus, which draws the stomach and diaphragm upwards, whilst at the same time the diaphragm itself experiences a convulsion which draws it downwards.”* It is, however, very questionable whether the œsophagus ever executes movements of the kind here supposed. With regard to the peculiar

noise which accompanies hiccup, there can be little doubt that it is caused by a convulsive or spasmodic action of the muscles about the glottis.

There are two convulsive affections which, without being absolutely identical with ordinary hiccup, so nearly resemble it, that they are designated by the same word, at least in some languages, and must apparently be referred to nearly the same muscular powers. Thus, what is properly called the *hiccup of death*, although owing its name to a similarity to the true hiccup, in some respects differs from it. According to Double, it consists of two quick and forcible inspirations preceding a feeble and protracted expiration. The affection which we call *sobbing* is so analogous to hiccup, that, as has been before observed, the Greeks and Romans designated both by the same words. Indeed, not only do they nearly resemble one another, but sobbing in children often passes into perfect hiccup.

Having considered the mechanism of the affection, we may next advert to its *causes*, and the circumstances under which it occurs. In relation to these points, all the cases which are met with may be referred to two general heads, according as the hiccup is or is not preceded or accompanied by some other recognized morbid affection, of which it may be considered a symptom or consequence. It will be convenient to designate these two divisions by the terms symptomatic and idiopathic, although the strict propriety of such words is questionable.

By far the most frequent cause of *idiopathic hiccup* is some impression directly made upon the stomach; as, for example, by very hot or highly seasoned food, especially in a liquid form; by alcoholic and other stimulant liquors; and by food swallowed hastily, or in too great quantity, especially after long fasting. As the affection, when produced by causes of this kind, generally occurs almost immediately after the irritating matter is taken into the stomach, it may be reasonably inferred that the impression upon that organ, which calls forth the muscular efforts by which the hiccup is effected, is chiefly made upon its cardiac extremity; and we shall hereafter see that one mode of explaining the final cause of the affection is by a deduction from this opinion.

The occasional causes just enumerated evidently act upon the sensibility of the lining membrane of the stomach; but there are others which seem to operate by a mechanical impulse communicated to the whole organ. Thus, in children more particularly, any vehement or convulsive movement of the respiratory muscles, as violent crying and sobbing, or a fit of coughing, is apt to end in hiccup. The same occasionally happens with vomiting, as was observed by Hippocrates, who noted it as an unfavourable occurrence.

A cause of a very different description from the above is fasting. It implies a prolonged absence of the proper and accustomed stimulus of the stomach; and the influence of this negative impression seems to afford a more probable explanation of the occurrence than the hypothesis

* Un mouvement convulsif de l'œsophage, qui tire en haut l'estomac et le diaphragme, tandis qu'en même tems le diaphragme lui-même éprouve une convulsion qui le tire en bas.”

which has referred it to the supposed irritation of the gastric juice.

Idiopathic hiccup, though generally, is by no means exclusively produced by causes directly influencing the stomach. Emotions of the mind, copious evacuations, as bleeding and purging; cold applied to the surface of the body, as the epigastrium, feet, &c.; and in fact, where there is a predisposition to it, almost any impression, external or internal, may call it forth. John Hunter observes that it often accompanies local irritation after operations of various kinds. To inquire whether such causes determine the muscular movements by which hiccup is effected, through the medium of an intervening impression upon the stomach, would be a fruitless indulgence in speculation.

The tendency of occasional causes, of whatever kind, to induce this affection, is of course very much dependent upon the degree of predisposition in the individual. This may perhaps be stated in general terms to arise from the same circumstances as those which appear to favour the occurrence of other convulsive movements, and especially from that condition of the system which is expressed by the common but indefinite terms of debility and irritability, or mobility. Thus it is familiar that childhood and old age are more liable to the affection than the middle periods of life; and that the female sex, especially in the puerperal state, is more subject to it than the male. There seems, however, to be ground for a more definite view of the matter, and for referring the predisposition, at least in a majority of cases, to a preternatural sensibility of the stomach, or to a tendency in that organ to functional derangement. Such a condition or tendency is well known to exist in the earlier and later periods of life, and during gestation; and it is probably owing to its presence in an unusual degree that, in some individuals, even a moderate quantity of the mildest food will often cause a fit of hiccup. Indeed in such persons it not unfrequently occurs without the intervention of any known cause.

The predisposition, in whatever it consists, may be either original or acquired. In the latter case it can sometimes be traced to debilitating circumstances, as excessive evacuations; but it is much more commonly attributable to causes which directly impair the digestive powers, as the abuse of ardent spirits, excesses in diet, &c.; and such an impaired state of the function of digestion is probably one principal cause of the peculiar liability of old people.

Idiopathic hiccup is commonly too slight and transient an affection to merit the name of disease. Sometimes, however, by its violence, but more often by its duration, it assumes a graver character, and has even appeared to be fatal, as will be more particularly stated when the terminations of the affection come to be considered. It has occasionally been observed to recur periodically, at regular intervals, as, for example, annually, and at the same period of the year. Thus Heberden speaks of cases, some of them unaccompanied by any other appreciable morbid affection, in which it lasted

for many months, and even for years, being in some constant, in others intermitting. Dr. Good also refers to cases in which it returned at irregular intervals, for periods of from four to twenty-four years; and in others in which it continued incessant, or nearly so, for eight and twelve days, and even three months.

The second division of cases of hiccup includes those in which it co-exists with, and appears to depend on, some other disease as its cause; being then what we call a *symptomatic* affection. It has been noted by authors as occurring principally in the following diseases:—fevers, both continued and intermitting, especially the latter; a complication which seems to have been formerly not uncommon, as the epithet *singultuosa* was applied to fevers accompanied by hiccup throughout their course; inflammation of the stomach, bowels, and liver; peritonitis, perhaps more particularly when the peritoneal coat of the diaphragm is involved; strangulated hernia; irritation of the mucous membrane of the alimentary canal, including worms, dentition, and the operation of poisons; disorders of the digestive function generally, especially when attended by the acid eructations which cause heart-burn; jaundice; uterine irritation, whether connected with gestation or not. Thus severe and protracted hiccup has been sometimes observed as one of the attendants of hysteria. It is also enumerated by some authors among the symptoms of inflammation of the spinal cord or its membranes; and Heberden states that it sometimes accompanies paralysis, and precedes epileptic fits. Of more uncommon instances, one deserves to be mentioned, because the hiccup is said to have been fatal. It is a case related by Bobe-Moreau, and cited by De Lens (*Art. Hoquet, Dict. des Sc. Méd.*) in which a severe hiccup accompanied an abscess in the upper part of the pharynx; and the death of the patient is ascribed to the symptomatic rather than to the primary affection. Some accidents affecting the diaphragm and neighbouring parts are also stated to be more or less commonly followed by hiccup: such are penetrating wounds of the abdomen, the passage of any of the abdominal viscera through the diaphragm into the thorax, fracture of the ribs, and depression of the ensiform cartilage.

As the most frequent cause of idiopathic hiccup is some direct irritation of the gastric mucous membrane, so by far the most common morbid affection on which the symptomatic variety depends, is functional or organic derangement of the stomach, and of those organs which are associated with it in the digestive process; a derangement of which habitual excess, particularly in the use of ardent spirits, is undoubtedly the principal origin. With regard to the mode in which the other diseases and accidents above enumerated give rise to hiccup, we seem to have no adequate data upon which to reason, and mere speculation would be worse than useless. It will, however, be seen that most of them either directly involve the digestive organs, or others which are known to have a close sympathy with them. The occur-

rence of hiccup in some of these cases can scarcely be accounted for except by supposing a considerable predisposition to exist; and the same may be said of its appearance under certain circumstances in which it is not strictly referable either to the symptomatic or idiopathic form, but immediately follows the disappearance of some previously existing disease. The most common case of this kind is the sudden cessation of ague, of which numerous examples are found in the older writers. Among others, Fred. Hoffmann mentions instances in which the hiccup assumed both a continuous and periodical form. It has also been observed to ensue upon the disappearance of continued fever, gout, rheumatism, and cutaneous diseases, and upon the cessation of a natural or accidental evacuation, as the menses, hemorrhoids, and diarrhœa. When originating in this way, it is sometimes very tedious and obstinate; as, for example, when connected with amenorrhœa, not ceasing till the menstrual evacuation is re-established.

Among the circumstances which determine the occurrence, or rather the continuance of hiccup, we must include the force of habit. The influence of this cause is seen in most if not all of the convulsive movements to which the body is liable; and in none more so than in the one now under consideration.

Of the terminations of this affection little need be said. When unconnected with any other severe malady, it almost invariably disappears sooner or later, though its duration is, as we have seen, sometimes very protracted. Cases are, however, reported to have occurred, in which the hiccup itself was the cause of death. One has been already adverted to, in which it was symptomatic. The same author (Bobe-Moreau) relates another, also complicated with difficult deglutition, and speedily fatal; but no cause of the hiccup was discovered by dissection; nor have we any thing beyond conjecture to explain the fatal termination. De Lens, apparently following some preceding authority, states that prolonged hiccup produces swelling and redness of the face; thus implying the possible occurrence of cerebral congestion or of suffocation.

It has been before stated that hiccup sometimes follows and takes the place of other convulsive movements, in the production of which the respiratory muscles are chiefly concerned. In like manner it occasionally terminates in them. The most common instance appears to be that of sneezing: thus Hippocrates says, if hiccup be restrained, sneezing comes on, and the hiccup ceases; and Lanzoni and Bartholin met with hiccup alternating with violent sneezing after tertian ague.

Having thus mentioned most of the facts relating to this affection which seem worthy of notice, it will be proper to make a few remarks on what may be called its *final cause*. In many of the convulsive movements of the body, such as coughing, sneezing, and vomiting, this is in general sufficiently obvious, being either the expulsion of offending matter, or the protection of the irritated part by exciting secretion,

or the restoration of its interrupted circulation and functions. In others, as epilepsy and often asthma, the existence of such a cause, though not admitting of demonstration, seems deducible from a just analogy; and the same may be said of hiccup, at least when excited by some direct irritation of the stomach. In such cases, the final cause is evidently not the rejection of the offending matter; for this would be effected by the act of vomiting, which hiccup has little or no tendency to induce. It is conceivable that one end to which it is directed is the propulsion of the irritating matter towards the duodenum; and thus the final cause has been conjectured to be the removal of such matter from the cardiac extremity to a less sensitive part of the stomach. However this may be, it seems probable that the hiccup subserves another and perhaps more important purpose,—that of determining so much of vital energy to the organs of digestion, especially the stomach, as shall counteract the morbid influence exerted upon them, and induce a vigorous performance of their functions. Such a view well accords with that pleasurable sensation, referred to the epigastric region, which is stated often to follow a fit of hiccup. The same may be said of a fact already mentioned, the occurrence of hiccup as a termination (sometimes apparently a critical one) of continued and intermittent fevers, and also of its occasional appearance at the commencement of eruptive fevers. To these may be added another, mentioned in the first report made by Drs. Russell and Barry, on the cholera at St. Petersburg. These gentlemen observe it is “singular enough to say, hiccough coming on in the intermediate moments between the threatening of death and the beginning of reaction, is a favourable sign, and generally announces the return of circulation.”

Undoubtedly the above view of the final cause is most obviously applicable to those cases in which the hiccup appears as the effect and remedy of a temporary irritation; but it is by no means incongruous with others in which the affection is symptomatic of some grave or fatal lesion. The parts of our frame are so associated by that inexplicable bond which we call sympathy, that irritation in one organ commonly gives rise to a morbid condition or movement in others. This association is governed by certain general laws, often very imperfectly known to us, but the great end of which is manifestly the preservation of the whole body; and the operation of these laws continues, not only when it cannot produce any beneficial effect, but even when it becomes absolutely pernicious. Thus the hiccup which ushers in death is a fruitless effort of nature; while that which results from abdominal wounds, inflammation, or herniæ, may not only be inadequate to accomplish any good purpose, but may even aggravate the existing evil by a repeated concussion of parts which stand in need of perfect rest.

In relation to *diagnosis* generally, the presence or absence of hiccup does not appear to be a guide of much value, since it is pathogno-

monic of no one morbid affection, but appears under widely different circumstances, from an inconsiderable and temporary irritation to the most formidable and fatal lesions. In cases which present general indications of severe abdominal disease, but not such as enable us to localize it, hiccup may indeed point to some two or three organs more particularly, but it cannot justify us in allocating the disease in any one of them rather than in the others.

As a ground of *prognosis* it may be more valuable; though, for the reasons just stated, scarcely so much so as has been generally represented. Conjoined with other symptoms which portend death, it of course strengthens the evidence of its approach; and when it occurs in affections which have produced great prostration of the vital powers, it no doubt generally implies an expiring and ineffectual struggle of nature. Thus Hippocrates speaks of it as an alarming symptom after hemorrhage, vomiting, and purging; and Sydenham appears to have verified the observation, especially with reference to the aged. It is, however, to be borne in mind that even in such circumstances it sometimes indicates (as already stated of cholera) a successful effort of nature to bring about a salutary reaction.

It is not necessary to say much about the *treatment* of an affection which is mostly either too inconsiderable and temporary to call for medical aid, or else a mere symptom of some more formidable malady. In the slighter cases of idiopathic hiccup in which its recurrence seems chiefly the effect of habit, impressions of various kinds, made either upon the organs more immediately concerned, or upon the body generally, are adequate to remove it. Such are the emotions of surprise and fear, a forcible suspension of the act of respiration, sneezing, vomiting, protracted deglutition by sipping liquids, the administration of what are called antispasmodic medicines, including opium; of stimulants, as oil of anise, mint, &c.; of mineral acids, alkalies, and bitter tonics, especially quinine; cold aspersion of the body, &c. The efficacy of many of these remedies is no doubt partly or principally owing to their removing those disorders of the digestive function of which hiccup is so often a symptom.

In cases of a more severe or obstinate nature, cupping at the epigastric region, the application of blisters, sinapisms, and warm plasters to the same parts, and opiate friction, have been resorted to with success. Borrichius relates a case in which the affection returned annually at the same period, and each time yielded to a copious bleeding; a fact which illustrates the remark of Hippocrates, that hiccup, like spasm, may result from repletion (*πληρωσις*), as well as evacuation (*κένωσις*). When it depends upon causes of the latter class, opium is undoubtedly, as Sydenham has told us, the best remedy; and the same may be said of those cases of visceral disease or lesion, in which, supposing recovery to be hopeless, we must still attempt to remove, or at least to mitigate, a distressing symptom.

(Edward Ash.)

HOOPING-COUGH.—Hooping-cough has been described under a variety of names, many of which, as chin-cough, kink-cough, &c. refer to its prominent symptom. In France it is usually termed *coqueluche*; in Germany, *keuchhusten*, *stickhusten*, &c.; in Scotland *kinkhoast*. It was called *tussis convulsiva* by Willis, *tussis ferina* by Hoffmann.

The nosological term at present most generally employed to express the disease is *pertussis*, first given to it by Sydenham, and afterwards adopted by Cullen, who arranges it under the class *Neuroses*, order *Spasmi*. His definition of the disease is the following:—"Morbus contagiosus, tussis convulsiva, strangulans, cum inspiratione sonora, iterata, sæpe vomitus."

In the above definition may be found Cullen's opinion as to the contagious nature of the disease. Doubts have, however, been raised upon this point by Laennec, Desruelles, and others, though not supported in such a way as to invalidate the common notions upon the subject.

The disease appears to have two distinct stages. The first lasts generally from ten days to a fortnight, or even three weeks, and is not different from an ordinary catarrh; there is cough and coryza often with very little fever. At the end of a period varying from one to two or three weeks, the second stage commences, and is distinguished by the peculiar convulsive cough. In this cough a number of expirations are made with such violence, and repeated in such quick succession, that the patient seems to be almost in danger of suffocation. The face and neck are swollen and livid, the eyes protruded and full of tears; at length one or two inspirations are made with similar violence, and by them the peculiar *whooping* sound is produced: a little rest probably follows, and is succeeded by another fit of coughing and another whoop; until, after a succession of these actions, the paroxysm is terminated by vomiting, or a discharge of mucus from the lungs, or perhaps by both. Sometimes when the *kink* is unusually severe, blood is forced from the nose, ears, and even from the eye-lids; and occasionally it ends, without producing any discharge, in the complete exhaustion of the patient.

The number of paroxysms occurring during a day varies much in different cases, according to the severity of the disease; and the violence of each is diminished in proportion to the freeness of the expectoration. After the disease has continued at its height for two or three weeks, it begins naturally to decline; the paroxysms become less frequent and violent, the expectoration increases, the cough soon loses its peculiar characteristics, and finally wears away altogether, leaving the patient in perfect health. It is to be observed, however, that occasionally, several weeks after the cough has entirely subsided, it may return; and for a long time, if the patient accidentally catch cold, the cough will often assume the spasmodic character, and be accompanied with "the whoop."

We may safely assert, notwithstanding a con-

trary surmise advanced by some of the French writers, that hooping-cough rarely if ever affects the same individual twice; and as its usual period of occurrence is during childhood, we shall of course seldom meet the disease among adults.

It is also supposed to be very uncommon in early infancy (for the first two months)—an opinion which is generally true, although we have seen more than one instance of an attack in children three weeks old. When the disease attacks an adult, it generally wants the peculiar whooping inspiration, and the same thing is usually, but not constantly, observed in the cases of very young children.

Nature and seat.—A great variety of opinions have been advanced by different authors respecting the nature of hooping-cough; all, however, that have any bearing on practice may be reduced to the three following:—

1. It was considered to be essentially spasmodic, and to arise from irritation affecting either the brain or some parts of the nervous system, a theory advanced and variously modified by Cullen, Leroy, Löbenstein, Jahn, and Webster.

Dr. Webster's opinion is "that the actual seat of hooping-cough is in the head, and that the affection of the respiratory organs is only to be considered as a secondary effect, or as an effort of nature to relieve herself by expanding the lungs to an unusual degree, and thereby allowing a greater quantity of blood to flow into them, which may in some degree diminish the fulness and congestion in the head."^{*}

Löbenstein and Breschet favoured the idea of the disease having its origin in the phrenic and pneumogastric nerves.

2. A great number of celebrated names may be enumerated in support of the opinion that it is always an inflammatory affection of the bronchial membrane; amongst these are Guersent, Watt, Marcus, Laennec, Dewees, &c.

As the attention of Dr. Watt was particularly directed to hooping-cough attended with bronchial inflammation, in consequence of the death of two of his children from this cause, we shall here give an abstract of his general conclusions on the subject. According to him, "it is in all cases an inflammatory disease of the mucous membrane of the larynx, trachea, bronchi, and air cells;" and when mild, he says it may run its course without materially disturbing the other functions of the body, or even the functions of that very membrane where it is seated; and that, whenever it proves dangerous or fatal, it does so by the degree of inflammation in the natural seat of the disease, or by that inflammation extending or being translated to other parts.† Dr. Dawson differs from the other writers who support the inflammatory origin of hooping-cough, in confining its first seat to the membrane of the larynx, or, strictly speaking, of the glottis.‡

3. Some consider the disease to be at first

inflammatory, afterwards spasmodic. Desruelles advanced this opinion, and proposes to designate hooping-cough by the term "broncho-cephalite." According to him the disease consists of an inflammation of the bronchi complicated with irritation of the brain, the bronchitis being always primitive, the cerebral irritation always consecutive. So long as the bronchitis is simple, the cough has nothing peculiar; but as soon as the cerebral irritation occurs, the diaphragm and respiratory muscles, and those of the glottis and larynx, are drawn into spasmodic action, and the cough changes its character and becomes convulsive.

This theory has the great recommendation of being in accordance with the practice which has been found most beneficial in the treatment of the disease; and it has been justly remarked that the effects of remedies, if accurately observed, are like chemical tests, frequently the means of detecting important differences in objects which otherwise could not have been distinguished from each other.

Amongst so many different opinions respecting the nature of the disease, and the sources from which danger most frequently arises, the young practitioner is left without any steady guide to regulate either his prognosis or his practice.

There can be little doubt that much of this confusion has arisen from the attention of practitioners having been directed so particularly to certain complications as to lead them to overlook the simple disease itself. In order to avoid this error, and to give (as it is hoped) a clearer view of the subject, we shall consider hooping-cough under the four following divisions:—

1. Simple hooping-cough.

2. Hooping-cough complicated with bronchitis or peripneumony.

3. Hooping-cough complicated with disordered bowels or infantile remittent fever.

4. Hooping-cough complicated with convulsions or hydrocephalus.

1. *Simple hooping-cough.*—The disease may be called *simple*, where, after it is fully formed, the fits are neither frequent nor violent, the expectoration is moderate, and the child during the intervals of the cough is quiet, retains his appetite, sleeps well, and without fever or difficulty of breathing. A child will be playing apparently in good health, when suddenly he drops his playthings, rushes out of the room, and is heard to cough, whoop, and discharge the contents of his stomach; immediately after which he returns, calling out loudly for something to eat. In a few minutes after the paroxysm, his pulse will be quite tranquil; and if the stethoscope be applied to his chest, the respiration will be heard perfectly natural, without any mixture of wheezing.

In such a case the disease must be considered almost, if not altogether, free from danger, and it is scarcely reasonable to suppose the existence of bronchial inflammation.

It may be said that cases of this description are rarely to be met with, and this must be admitted; but if children always lived in pure air, and were in perfect health when attacked

^{*} Med. and Phis. Journal, Dec. 1822.

† Treatise of Chicough, Glasg. 1815.

‡ Nosological Practice of Physic, London, 1824.

by the disease, and if it occurred during the summer season, such cases would be much more frequent.

As this combination of favourable circumstances, however, rarely occurs, so we seldom meet the disease in this simple form; but its occurrence even in a single instance decides the question that the disease, in the second stage at least, is not necessarily inflammatory, as we can hardly presume an inflammation to exist without any symptoms of inflammation being present.

2. *Hooping-cough complicated with bronchitis or peripneumony.*—The symptoms of this complication, though sometimes obscure, are generally well marked. According to Cullen, hooping-cough hardly ever proves fatal without considerable dyspnoea having existed for some time. It would appear that in older children, when the disease proves fatal, it is most commonly in consequence of inflammation supervening in the mucous membrane of the lungs. In very many instances where the state of the lungs was ascertained by dissection, the most remarkable phenomenon that presented itself was an inflamed condition of the bronchi, which were almost entirely plugged up with frothy mucus and sero-purulent fluid.

A point of the greatest importance in the treatment of the disease is to watch the earliest symptoms of bronchitis, as upon their speedy removal will principally depend the safety of the patient.

We are warned of the occurrence of bronchitis when the pulse becomes permanently quick, small, and hard; the fits of coughing become more frequent and more distressing, and the breathing is hurried in the intervals of the paroxysms; when any exertion or speaking causes increased difficulty of breathing or panting; the lips acquire a livid hue, and the extremities shew a great tendency to become cold.

As the disease advances, the pulse becomes more frequent, the difficulty of breathing increases, the *alæ nasi* are alternately contracted and dilated, and there is great prostration of strength; in many cases the cough is nearly suspended, and when it does occur, it is not accompanied by the usual whoop, and the difficulty of getting up the mucus is greatly increased.

The respirations vary from 60 to 100 in a minute; and if, after having maintained this frequency for twenty-four or thirty-six hours, they come down to 40 or 50, the change generally indicates recovery.

There is considerable and permanent wheezing for the two first days, not audible unless by aid of the stethoscope or by applying the ear to the chest, after which it increases and becomes quite perceptible by laying one hand on the chest and the other on the back. The wheezing is greatest after sleep, or immediately before a paroxysm of coughing.

When the bronchial inflammation cannot be checked, the breathing becomes more hurried and laboured; the wheezing increases; stupor

and prostration succeed; the cough is suspended; the pulse becomes nearly imperceptible; the extremities cold; and in the course of eight or ten days from its commencement death ensues from the accumulation of mucus, which apparently produces suffocation.

When the attack terminates favourably, the breathing becomes less hurried, the wheezing diminishes, the cough after a temporary suspension returns, the fever subsides, the countenance assumes a more healthy appearance, and quiet sleep succeeds to distressing restlessness.

On examination after death, the most usual morbid appearance is inflammation of the mucous membrane. The lungs collapse imperfectly, and when cut into, an abundance of frothy and puriform mucus exudes from the bronchi and air-cells. Increased solidity of the lung has often been found, and by some it is said to be constantly observable. When it does occur, it would appear that the inflammation had extended from the mucous membrane to the substance of the lung, or attacked both its textures.

3. *Hooping-cough complicated with disordered bowels or infantile remittent fever.*—These, though present, are much less formidable combinations than the last, but still they render the disease very intractable.

If we find a child in this disease breathing heavily, with foul tongue, loss of appetite, tumefied belly, and the discharges from the bowels unnatural in colour, consistence, or smell, we may rest assured that, unless these symptoms are removed by the prompt use of medicine calculated to effect that purpose, much distress will eventually ensue. Infantile remittent fever will next arise, and this may itself prove fatal, or lead to hydrocephalus.

A great number of the long-protracted cases of hooping cough are complicated with remittent fever. After the symptoms just enumerated have continued for a longer or shorter time, the fever makes its appearance, sometimes commencing with a rigor; more frequently, however, it comes on so gradually, that we do not know precisely when to date its commencement. The paroxysms of coughing become more frequent, and the breathing is quickened and oppressed; but still it may be with a little care distinguished from the attack of bronchial inflammation. The stethoscope affords us useful though negative evidence. The usual symptoms of bronchial inflammation are absent. The frequency and force of the respiration are found increased, but this increase is not accompanied by any râle indicative of bronchial inflammation; while the daily remissions, the loaded tongue, the nature of the alvine discharges, the aspect of the child constantly picking his nose and lips, all serve to determine the true character of the disease.

4. *Hooping-cough complicated with convulsions or hydrocephalus.*—Every one who has seen much of hooping-cough is aware that when it occurs during the period of dentition, it is frequently accompanied by convul-

sions, and that they are among the principal sources of danger at that age.

This complication may be accounted for in like manner as the bleeding from the nose, ears, &c.—namely, by the interruption given by the violence of the cough to the free return of blood from the head, and also by the circumstance of children being so liable to convulsions at this period of their lives.

It is said that the child may be carried off by one of the convulsions: this, however, very rarely happens. After their frequent return, the case may pass into hydrocephalus.

In a child from seven months to two years of age who has the hooping-cough, if we observe that the paroxysms become suddenly increased in violence, that the thumbs are drawn into the palms of the hands, while there is no accession of bronchial inflammation to account for the increase of cough, we may apprehend convulsions. If, however, in addition to these symptoms, the child, after each fit of coughing, instead of whooping becomes livid, we may calculate to a certainty on convulsions, if suitable means be not employed to ward them off. If the child has ever had the swelling of the top of the fingers and toes, noticed by Dr. Kellie of Leith, or that peculiar spasmodic affection described by Dr. Clarke and more recently by Dr. Marsh, under the title of Spasm of the Glottis, (see GLOTTIS, SPASM OF,) we can scarcely expect that it will pass through the hooping-cough without an attack of convulsions.

It is sometimes important and always desirable to be able to say if the convulsions in these cases depend upon disease in the head; and rules have been laid down for ascertaining this point, but they are not altogether unobjectionable. It is said, that in hydrocephalus one side of the body is more affected than the other, but in convulsions which are independent of organic disease of the brain, that both sides are equally affected. If the convulsions are distinctly confined to one side of the body, there is every reason to fear the existence of hydrocephalus; but it certainly does not follow, because the convulsions are general, that the brain is unaffected. In the latter case we must wait until the convulsions subside before we can discover their cause, and then we must form our opinion from the general state of the child and the history of the case, rather than from any peculiarity in the convulsion itself.

When hydrocephalus supervenes upon hooping-cough in a child under two years of age, it is almost uniformly preceded or accompanied by convulsions; occasionally, however, it creeps on more insidiously, and we have several times been called upon to see a child in a state of stupor, with one arm sawing the air, whilst the other side was paralysed; and yet neither the parents nor medical attendant were aware of the nature of the case, but were solely occupied in attending to the cough.

Where hydrocephalus prevails in the family, we must, whenever the children are

attacked by hooping-cough, be on the look-out for the earliest symptoms. If there are fits of drowsiness and languor, aversion to light or noise, occasional headache, screaming out during sleep, grinding the teeth, frequent sighing; after more or fewer of these symptoms, if the child is attacked with fever, accompanied by greater irritability of stomach than we can account for or than is natural in hooping-cough, and if, to use the words of Dr. Cheyne, "purgatives produce mucous rather than feculent stools," we may safely consider that our most strenuous exertions will be required for the averting of this formidable malady.

The approach of hydrocephalus in these cases has been occasionally overlooked in consequence of mistaking the laborious respiration arising from oppressed brain, and considering it to be the effect of bronchial inflammation. The assistance of the stethoscope would be here most valuable, but unfortunately the restlessness and crying of young children renders its application in many cases difficult if not altogether impossible, and we are often obliged to form our opinion from the character of the breathing. In hydrocephalus the breathing is not permanently quick; it is irregular and sobbing; occasionally the child sighs heavily, expanding the chest in a manner that never takes place in inflammatory affections of that cavity.

Prognosis.—It is generally supposed that hooping-cough is more dangerous in proportion to the youth of the child, and it is certainly true that the majority of its victims are under two years of age. It is, however, equally true that a healthy child under six months, who has a good nurse, will get through the disease better than one a few months older, who has been recently weaned, or in whom dentition has commenced. The following circumstances would lead us to give a favourable prognosis: dentition being completed, and the head, bowels, and lungs not being subject to determinations or irritations; the season of the year being mild and dry; the patient not suffering or not having recently suffered from any other of the diseases of childhood, and having a sound, healthy constitution; finally, the accessions being at long intervals, the remissions complete, and the night, during which the *symptoms are usually most severe*, well spent. In adults, owing to their greater strength of constitution and lesser liability to the diseases which usually produce a fatal result in hooping-cough, the prognosis will be more favourable.

General treatment.—The treatment of hooping-cough has always been considered as difficult; indeed it is generally admitted that, even in the mildest form, it will run its course without *much* interruption or abbreviation from medicine. From this consideration it would appear that in the *simple* hooping-cough very little medical interference is required; and judicious practitioners content themselves with giving every night a few grains of rhubarb and ipecacuan proportioned to the age of

the patient, with an occasional emetic; confining the child to a milk and vegetable diet, and, during the existence of the catarrhal symptoms, to an equable temperature. The latter advice leads us to speak of the popular error, too often countenanced by practitioners, of unguardedly exposing the child to cold and open air. We shall shortly find that change of air is often very beneficial in a later stage: but when the first or catarrhal stage exists, we should adopt the practice now recommended. Mr. Pearson's plan of treatment is applicable to the simple disease. He prescribes in the first instance an antimonial emetic, and afterwards, for a child of one or two years old, a draught containing a drop of tincture of opium, five drops of ipecacuan wine, and two grains carbonate of soda, to be repeated every fourth hour for several days. When purgatives are required, he gives rhubarb and calomel. As the cough subsides he diminishes the opiate, and substitutes gum myrrh in place of the ipecacuan wine. It is important to hold in mind that to patients labouring under hooping-cough, the great danger is from the complication with bronchitis; and in the treatment of the simple disease, our attention will be chiefly required to obviate this predisposition. The state of the lungs must be watched, and any approach to inflammatory symptoms met early by bleeding and purgatives, and (if the age of the child does not forbid) by tartar emetic. The latter medicine will also be found of use by facilitating the unloading of the stomach, which usually terminates a fit. Should the weather be cold, it will be well to have the child warmly clad, and to direct the use of flannel next the skin. When, under treatment of this kind, the disease gets through its course without any unpleasant events, and reaches the period of decline, we often find that although the patient be otherwise quite well, the cough will still continue. In such a case, when our interference appears to be necessary rather to break a habit than cure a disease, we shall often find change of air to be the very best remedy. At this period, also, antispasmodics and sedatives may occasionally be employed with advantage. The oxide of zinc has been recommended by Guersent in doses of a grain every hour for a child of six months old; and in a case of the disease with some threatenings of convulsions, we on one occasion found benefit from musk. The latter medicine has also been highly recommended to us by a practitioner of considerable experience.

A cough mixture, containing a small quantity of tincture of opium or syrup of poppies, will sometimes be of use, as will also the laurel water, or, in adults, prussic acid itself, administered with due caution. In cases where considerable debility exists, or the disease, towards its close, becomes manifestly intermittent, the tonic plan may be required, and sulphate of quinine will be found to act most beneficially in conjunction with change of air and diet.

Various external applications are popular in the treatment of hooping-cough, as the patent

medicine called "Roche's embrocation;" and the "pommade d'Autenrieth," composed of a part and a half of tartar emetic with eight parts of lard. These, however, are means very secondary indeed, in the treatment of any of the complications of the hooping-cough. In the simple disease embrocations which merely redden the surface can do no harm, and are sometimes useful, but applications containing tartar emetic or other violently stimulating substances, in addition to being unnecessary, very often produce pustules and ulcerations, which materially augment the sufferings of the patient.

Treatment of complications.—The first complications of which we have spoken are inflammation of the bronchial mucous membrane, or of the substance of the lungs itself,—bronchitis and peripneumonia. And in truth it is to the guarding against these affections that much of our attention and remedial measures must be directed in the treatment of the simple disease. When from the occurrence of the symptoms mentioned above, we have reason to suppose the existence of one or both of these inflammations, we must at once take decided steps to cut short the disease, if possible; or should that not be practicable, to promote the speedy expectoration or absorption of the fluids effused into the bronchi and air-cells. The means of effecting the first of these indications are obviously those applicable to similar inflammations under ordinary circumstances, in which we do not propose at present to enter. A few peculiarities, however, are to be attended to in their use, to which we shall briefly advert. In the first place, we must observe that in bronchitis supervening upon hooping-cough, a more free use of the lancet is warranted and required than would be advisable in other cases, and for the reasons already mentioned that it is proved both by the symptoms and appearances after death, that the substance of the lung is almost always affected. With respect to the employment of purgatives, we would also remark, that although it is very necessary to attend to the state of the bowels, still continued purging will be found to produce a degree of flatulence, which by exerting pressure upon the diaphragm will considerably increase the dyspnoea, irritate the mucous membrane, and needlessly debilitate. We shall occasionally meet cases attended with so much irritability of the stomach and bowels as to prevent altogether the use of either ipecacuan or antimonial medicines. In these instances, of course, our reliance must be chiefly upon the lancet, aided by blistering, the warm bath, and small doses of nitre. In following up the second indication, after effusion into the bronchi and air-cells has taken place to any extent, we must be very cautious about the further abstraction of blood; this stage being attended with considerable debility, and our object being to prevent such exhaustion as would interfere with the process of expectoration. It is at this period we may expect most benefit from blistering, both by arresting inflammation and

no?
no?

preventing further effusion.* To promote expectoration in older children, we may employ antimonials or a combination of calomel and ipecacuan in repeated doses. In very young infants, when the use of antimonials is not advisable, we may give an occasional emetic of ipecacuan wine and syrup of squills, and in place of calomel substitute hydrarg. cum cretâ in combination with pulv. ipecac.

We shall now turn our attention to the next train of morbid actions which we have mentioned as being occasionally attendant upon whooping-cough—a disordered state of the bowels and infantile remittent fever; and as these complications are rarely met with except in children, our observations principally apply to them. In speaking of the treatment of the simple form of whooping-cough, we alluded to the frequent occurrence of derangement of the bowels. This tendency exists in all acute diseases of children, and in practice it will be found that the most marked improvements in the symptoms of the original disease will attend the correction of the alvine discharges. It is important, therefore, to meet the symptoms indicating derangement of the bowels by keeping up their regular action. If actual constipation exists, active purgatives will be required. Nothing is better for children than a combination of scammony, rhubarb, and calomel in divided doses, repeated until a full effect be produced. For patients more advanced, one or two grains of calomel, or three or four of blue pill, followed by any mild purgative mixture, may be administered. When the secretions are merely altered in quality without constipation, mild laxatives only will be required, as rhubarb and hydrarg. cum cretâ in the younger, and blue pill and rhubarb in older patients. The state of disease we are speaking of has been accurately described by Dr. Hamilton as the first stage of marasmus, and some very judicious observations are made by him upon its treatment. Unfortunately, however, the fatal facility of the purgative system has led to its adoption in this affection to an extent that has been very injurious, and was certainly never authorized by that able physician. Where the purging has been carried to excess, tenesmus, scanty mucous stools, tenderness of the belly, and a degree of tympanitic fulness succeed, which greatly aggravate the cough. Our object must then be to allay irritation by warm fomentation to the abdomen, soothing enemata, and sometimes, when the tenesmus is very distressing, by the employment of opiate glysters. When the bowels are so irritable as to be acted upon by the force of each cough with fetid depraved stools, a state which sometimes occurs in whooping-cough, small doses of hydrarg. cum cretâ and Dover's powder, followed by castor-oil, usually gives relief. When the symptoms become decidedly those of remittent fever, it is to them we must

direct our treatment rather than to the original disease, as we shall always find the cough to become more distressing in a ratio with the increase of the fever, and on the other hand to be proportionately relieved by its decline. For the management of this form of fever we must refer to the article upon that subject. (See FEVER, INFANTILE REMITTENT.) We may remark, however, that the observations offered above upon the administration of purgatives are even more particularly applicable here. A torpor of the intestines often exists to so remarkable a degree, as to render doses of purgative medicine quite inert that would at other times be amply sufficient. This we have been in the habit of accounting for by the congestion that exists in the head, and accordingly have found in practice that when strong purgatives have had no action by themselves, abundant effect was produced by a much milder one employed after a general bleeding, or, if the strength of the child did not permit this, after the application of leeches to the temples or epigastrium.

The last formidable complications of whooping-cough we have noticed are convulsions and hydrocephalus. When any of the symptoms already mentioned as premonitory of convulsions occur, our treatment must be guided by what we can learn of their causes and tendencies in each particular case. The convulsions of children, whether they are idiopathic or complicated with whooping-cough, generally depend upon the irritation of teething, irritation of the alimentary canal, or disease of the brain itself; and the tendency most to be dreaded is the hydrocephalic.

The indications, therefore, are to remove these irritations by attending to the state of the gums, by regulating the action of the bowels, and obviating local determinations, particularly to the head. When, in spite of our best directed efforts, convulsions, as will be frequently the case, do supervene, they must be treated according to the general principles laid down for their management under ordinary circumstances. When the attacks recur frequently and baffle the usual means of cure, there are two plans by which we shall often be able to prevent their return: one is, a total alteration of the child's diet, the other a complete change of air. When the child affected is at the breast, defectiveness of quantity or quality will usually be detected in the nurse's milk. Often it will be found that she has menstruated, or, as sometimes happens, that, without the discharge actually occurring, she has experienced sensations similar to those which attend the accession of the catamenia. In such cases the milk almost uniformly disagrees, and here it is a good rule, whenever the convulsive attacks withstand ordinary treatment, to enquire closely into the state of the nurse, and if there be any grounds for suspicion, to have a young and healthy one procured. Change of air often in the most remarkable manner puts a stop to the recurrence of convulsions, and will be found particularly beneficial in those cases of spasm of the glottis to which we have already alluded.

* The practitioner must, of course, hold in mind the danger of incautiously applying blisters to children.

Both these means will also act most usefully in protracted attacks of whooping-cough, even where there is no tendency to convulsions.

For the treatment of hydrocephalus, when it supervenes upon whooping-cough, we must refer to the article upon that disease. With respect to its prevention, the remarks made upon deranged bowels and convulsions are equally applicable as to those complications. One thing is to be remembered, that in conjunction with whooping-cough hydrocephalus is more than usually fatal, and requires our whole attention to its management.

Specific remedies.—An immense variety of these has been brought into notice, but if the views above offered be correct, their value will be less estimated. From what we have said of the simple disease, it will be seen that such medicines must be superfluous. Some of them from their violence are dangerous, and in the various complications it must be evident that no specifics are admissible. However, as some are strongly recommended, and may perhaps occasionally be of use in the decline of the disease, when the cough has become habitual, we shall give a list of the most remarkable, adding the names of those who brought them into notice.

HYDATIDS.—This word (derived from *ὑδαρίς, vesicula, ὑδωρ, aqua,*) has, in descriptive pathology, been indiscriminately applied to pellucid cysts containing a transparent fluid,* developed either in the cavities, or in various tissues of the human body, as well as in those of the inferior animals. These cysts, on minute examination, having been found to vary considerably in structure, and in some instances to possess the characteristics of animal life, an extended signification has been attached to the term, and it has been adopted as the name of an order of animals or animalcules, consisting of several genera and species.

It may be presumed that animal bodies have been subject to such vesicular formations from the earliest period, and the records of medicine abundantly testify that their occurrence has been commonly noticed from the time of Hippocrates to the present day, though, until a recent date, their real nature seems to have been little investigated. It must, however, be acknowledged that even up to the present time the term *hydatid* has a very indefinite meaning.

The general appearance of these bodies has probably had an influence in limiting the opinion entertained by medical men of their morbid effects to mechanical action, and experience has hitherto afforded no reason which invalidates it: it is to this cause probably that we must attribute the common notice of their occurrence by the early writers on medicine, without further description than that which the etymology of the word *hydatid* conveys; and as we find little in their observations which can serve to elucidate the subject, we shall endeavour to be very brief in showing how far they attracted their notice.

Hippocrates has adverted to them in his general application of the word growth, *φύμα*, particularizing this kind by the nature of the contents; and he seems to have been well aware of their occurrence in some of the inferior animals as well as in man. It is remarkable, however, that he has only noticed their presence in the chest, a part of the body in which they are not most frequently observed, and where they are in general acknowledged to be only simple cysts.

Such were probably the nature of those to which he has alluded as the precursors of anasarca and hydrothorax, and as occurring frequently in the ox, the dog, and in swine, quadrupeds in which he says growths on the lung, containing water, were most frequently found, as dissection testified:—"And such things (he adds) seem to be formed in man more than in cattle, inasmuch as our diet is more conducive to disease."^{*}

Aræteus alludes to a species of dropsy in the abdomen, *occasioned by several small bladders*, in proof of which he says, if the abdomen be pierced, a very small quantity of water escapes, these bladders including it; but their origin and nature he confesses were unknown to him, and adds that there were some who affirmed that bubbles of this kind passed through the intestines into the belly.† Celsus probably alludes to dropsy from the same cause in the observation, "*modo corpus inæquale est tumoribus aliter aliterque per totum id orientibus;*" but makes no direct mention of hydatids, or other reference to them.‡ Galen noticed the aptitude of the liver to generate them, and their frequent presence in this organ in animals killed without disease;§ they are referred to also by Ætius;|| and in the compilations of

* Περὶ τῶν ἐν τοῖς παθῶν, sect. v. p. 544.

† Lib. II. cap. i. 51.

‡ Lib. III. s. xxi.

§ Comment. in Aph. 55.

|| Serm. x. cap. 20, p. 234.

Bonetus, Morgagni, and Van Swieten, are introduced, from various sources, numerous observations on hydatids in man as well as in the inferior animals. The idea of the animal nature of hydatids, which appears to have first excited attention to the difference of bodies referred to under this name, was broached by Hartmann* in the year 1685, and was the result of a more particular examination than had been before instituted on some taken from the inferior animals; it was particularly suggested by his witnessing their motions when immersed in warm water: his observations, however, seem to have been unknown to our countryman Dr. Tyson, when in the year 1691 he published in the Philosophical Transactions (No. 193) a paper entitled "Lumbricus Hydropicus, or an essay to prove that hydatids often met with in morbid animal bodies are a species of worms or imperfect animals." It should be particularly borne in mind that Tyson's observations were made from hydatids found in the dissection of a gazella or antelope, and were consistent with a preconceived suspicion (by what circumstances suggested he does not inform us) that such hydatids were of the insect tribe, or at least their embryos or eggs. His reasons for this supposition, he states, were, first, that he observed them to be included in an outward membrane like a matrix, so loosely that, by opening it with his fingers or a knife, the inward bladder containing the lymph or serum seemed no where to have any connection or hold to it, but very readily dropped out, still perfectly retaining its contents:—secondly, from observing with the naked eye, that to the inward bladder there was attached a neck or white body more opaque than the rest of the bladder and protuberant from it, with an orifice observable at the extremity, which seemed to be occasioned by the retraction of some part of it inwards, serving, as he conjectured, the purpose of a mouth to suck the serum from the outward membrane, and so to supply its bladder or stomach, organs with which his imagination had also supplied it: thirdly, by finding, with the testimony of another observer, that this neck, on being approached to the flame of a candle, did really move, at first protruding, and then retracting itself. On further examination, two small strings or pipes were observed proceeding from the neck, and floating in the liquor, the object of which Dr. Tyson conceived was to convey from the mouth the pabulum of the animal, derived by suction from the outer involving membrane. "Perhaps some," he adds, "may be more inclined to think that the whole is but an egg or embryo of another insect formation, and that this bladder is as it were the amnion, and the outer coat that includes it the chorion;" but having observed the same peculiarity of construction in every one of several hydatids taken from a rotten sheep, he considered such a supposition void of probability. The hydatids of the human body Tyson seems also to have minutely exam-

ined, and the circumstances in which he found them to differ he has noted in the record of a case so illustrative of the subject and fortunate in its termination, that we deem it well worth transcribing in this place:—"Thus in a patient still living, and enjoying her health better than all her lifetime before, about ten years of age, I caused her right side to be opened a little below her short ribs, whence issued out abundance of limpid water; but what was most surprising, together with it a great many hydatids, that first and last we guessed there might come out about five hundred of these bladders: most were entire and filled with limpid water, of others that were too large for the orifice the films were broken, but in none of them could I observe the neck, though I was inquisitive to find it, which makes me think them to be different from our present subject; as are also those I have frequently met with in the ovaria of women who have died hydropical, which I take to be only the eggs contained there, which by an extravagant flux of humours into them are often swelled to that prodigious size that I have taken several gallons of liquor out of them." Dr. Tyson further adverts to hydatids without necks, which he had found in the bladder of a human subject. "I shall only add," he says, "that the lumbrici hydropici I have always found hanging to the membranous parts rather than included in the body of any of the viscera, as to the omentum peritoneum or the outward membranes that cover the stomach, liver, colon, or other intestines." Hydatids of this kind were afterwards examined by Pallas,* and named by him *tæniæ hydatigenæ*, from the resemblance of their heads to those of the common worm of that genus. They have been further recognized as animalcules and adopted as such in the classifications of Linnæus, Fontana, Muller, Bloch, Werner, Cuvier, Lamarck, Zeder, Rudolphi, and Laennec. With regard to hydatids of the human body, Pallas has noted that those which came under his examination were void of neck and head, but that they evinced considerable contractility, as was exemplified by the retraction of their coats on division with a knife, "and with such force as to be turned almost inside outwards." The insect nature of the former having been acknowledged, the property just noticed was considered a title to the credit of distinct animalcular life in the latter, which had hitherto been regarded as morbid products endowed with the mere organic life of the parts with which they were found in contact. The new hypothesis seems to have been generally received with little further examination, and to have gained additional confirmation by the observations of Dr. John Hunter, published in the first volume of the Transactions of a Society for the Improvement of Medical and Chirurgical Knowledge for the year 1793. In this paper are detailed the case and dissection of a subject, with the result of an examination

* Miscel. Zool. Ed. Hagæ Comitum, 1766, p. 157.

* Misc. Nat. cur. Dec. 2 A. 4to.

of some hydatids, taken from a collection found between the neck of the bladder and the rectum, compared with others which presented themselves in the abdomen of a rotten sheep. The just estimation of Dr. Hunter's evidence will induce us to draw largely on the information he has left on record; we cannot, however, but remark with regard to hydatids of the human body, that he has expressed himself in language presumptive of data acknowledged by him to rest only on probability, assuming the endowment of the highest functions demonstrative of animal life, for bodies in which the existence of the lowest order was a question yet undetermined. It is worthy of remark that the hydatids of the gazella examined as we have already stated by Tyson, were found in a situation in that animal corresponding to that of the human subject from which Dr. Hunter's specimens were taken.

From the period at which animalcular life became a distinctive characteristic of certain hydatids in the inferior animals, and that this property, though on more slender evidence, was assigned to some others which were found in man, the prevailing inclination among medical writers and in oral communication has been to appropriate the term hydatid to those apparently so endowed; hence they have been denominated true hydatids; and to other pellicular cysts, formerly so considered, the epithet false has been applied in contradistinction.

From the preceding remarks it will be obvious that things most diversified in nature have been incongruously confounded under one name, and that to view them in their clear light as well as to see their pathological bearings with any profit or advantage, they must be severally considered with the definite signification proper to the classes in which nature presents them. These appear to us to be three in number, the *first* of which comprehends those hydatids which evince in their structure and properties the unquestionable endowment of distinct animalcular life. The *second* consists of such as have no evidence of animalcular life either in their construction or properties, but which has been assigned to them from certain phenomena, presently to be noticed, connected with their situation and growth. The *third* division embraces such as are universally admitted to have no place in the animal kingdom, but which may be regarded as excrescences or morbid formations, arising out of the natural tissues and organs of animal bodies.

The animalcular hydatids to which our first division refers have been observed to vary considerably in their structure, and have been ranged by naturalists in four distinct genera placed in the order *Vermes*, and thus designated, *H. cysticercus*, *H. polycephalus*, *H. ditrachyceros*, and *H. echinococcus*: to these a fifth genus has been added, constituted by the hydatids of our second division, the real nature of which, to say the least, is questionable, though they are commonly considered to belong to the insect tribe, and described as such under the name of *H. acephalocystis*.

The occurrence in the human body of the first four genera, and their specific consequences, have been little if at all investigated by the pathologists of our own country, and we find recorded by them only a single case in which any of them are particularly referred to. This case appears in the tenth volume of the London Medical Journal, but contains merely the statement that the patient had voided a number of *tæniæ hydatigenæ*, a name synonymous with the cysticercus of the above classification, and with the lumbricus hydropicus of Dr. Tyson, which, as we have already stated, was described by him and also by Dr. Hunter from specimens taken from the inferior animals. That their occurrence in the human body is not frequent, we infer from their having been rarely noticed by writers on pathology or medicine; but as minuteness of structure may have been more frequently overlooked than we have reason to suppose, and as they have been particularly adverted to on high authority, the following description, for which we are indebted to the labours of Cloquet,* will, we conceive, be an acceptable guide for future comparison and enquiry.

Genus 1. Hydatis cysticercus, Rudolphi; from *κυστίς, vesica* and *κέρκος, cauda*. Body nearly cylindrical or slightly depressed, wrinkled, terminated by a caudal vesicle; head furnished at its base with four parts or suckers.

Sp. 1. Cysticercus tenuicollis, Rudolphi. Syn. vermis vesicularis, Hartmann; hydra hydratula, *Linnaeus*; *tænia hydatigena, Pallas*; vermis vesicularis eremita, *Bloch*; hydatigena orbicularis, *Goeze*; hydatigena globosa, *Batsch*; vesicaria orbicularis, *Schrank*; *tænia globosa, Gmelin*; hydatis globosa, *Lamarck, Bose, Brugnières*; cysticercus lineatus, *Laennec*; cysticercus globosus, *Zeder*.

Character.—Head almost tetragonal, snout cylindrical, a little crooked, neck short, body small, caudal bladder nearly spherical. *Habitat*.—The peritoneum and pleura of ruminating animals, and of swine, especially in sheep, oxen, and goats, in the stag, the roebuck and gazella. A single instance is cited by Goeze of this species of hydatid having been found in the plexus choroides of an apoplectic human subject.

Sp. 2. Cysticercus cellulosus, Rudolphi. Syn. finna humana, Werner; *tænia hydatigena ovilla, Fischer*; *tænia cellulosa, v. finna, Gmelin*; vesicaria hygroma, *v. finna, Schrank*; hydatis finna, *Blumenbach*; vermis vesicularis, *Brera*; cysticercus finna, pyriformis, albo punctatus, *Zeder*; *tænia hydatigena anomala, Steinbach*; cysticercus finnus, *Laennec*.

Character.—Body conoid, from four to ten lines in length, caudal bladder ovoid, formed by a thin membrane, equal, transparent, without fibres; head tetragonal, furnished with four suckers, and thirty-two hooks divided into two rows. *Habitat*.—The hog, in which animal it causes the disease commonly known under the name of leprosy.

* Dict. des Sciences Méd. Art. *Hydatid*. Paris, 1818.

The word *finna* applied to this species of hydatid is of German extraction, from *finnen*, the name of this disgusting affection. Werner is reported to have found this species of hydatid in man.

Sp. 3. *Cysticercus fischerianus*, *Laennec*. Body round, very slender, annulated; head larger than the neck, furnished with suckers and crooks; caudal bladder pyriform, three or four lines in length, united to the body by its large extremity, and terminating in a point which adheres to the viscus which this worm inhabits. No cyst. *Habitat*.—This hydatid has been found twice in the plexus choroides of the human subject, by M. Fischer of Leipsic. It is yet but little known.

Sp. 4.—*Cysticercus dicystus*. This worm has been observed but once, and then by *Laennec*; he met with it in the ventricles of the brain of a man who died of apoplexy. It presents two pretty large bladders; one of these is caudal, whilst the other encloses the body anteriorly. This, which consequently is only developed in a bag which forms part of the animal itself, is conical, annulated, composed of an outer membrane of a yellowish colour, rather transparent, and of an anterior substance, white and rather bluish, and almost opaque. It is crossed by a large canal, terminating in a cul-de-sac at the side of the head, but which at the other extremity communicates with the caudal bladder. The number of hooks of the head is undetermined. It has only four suckers.

Sp. 5.—*Cysticercus albo punctatus*. M. Treutler is the only person up to the present time who has observed this hydatid; he found it in the plexus choroides of a woman who died at twenty-two years of age.

The body of this hydatid is three times longer than the caudal bladder. M. Treutler thought that he distinguished, with the aid of a magnifying glass, one sucker and six hooks. The caudal bladder is spherical and sprinkled irregularly with small white points.

Genus 2.—*H. polycephalus*, *Zeder*; *cænu-rus*, *Rudolphi*, from *πῶλος*, *multus*, and *κεφαλή*, *caput*. The derivation of the name of this genus explains its principal character. There are two species of it, viz. the *P. cerebralis*, and the *P. granulatus*; but as neither of them has been found in the human species, we shall pass on to

Genus 3.—*H. ditrachyceros*, from *δις*, *bis*, *τραχὺς*, *scaber*, and *κέρας*, *cornu*. Only one species of this vesicular worm has been noticed, viz. the *D. rudis*. The following is its character: Body oval, a line and a half long, flattened, terminated in a point posteriorly, enclosed in a membranous bladder, furnished anteriorly with a bifurcated horn, which appears rough to the naked eye, and, seen through a microscope, to be thick-set with straight and long scales. In which particular organ is the usual nidus of this hydatid is unknown. The specimens which Sultzter had an opportunity of observing had been expelled by stool from a young woman after having taken a purgative.

Genus 4.—*H. echinococcus*, from *ἰχθῦς*, *echinus*, and *κύκλος*, signifying a body of a round form with asperities, which characterize this genus.

Sp. 1.—*E. hominis*.—*Character*. Body pyriform, retracted towards the part where it adheres to the common bladder, one row of hooks on the head.

This species of hydatid was first found by M. Meckel, and afterwards by Zeder, in the brain of a young woman. They were about twelve in number, and occupied the third and fourth ventricles.

Of the nature and effects of these hydatids in the human body little is yet known, their characteristic distinctions having been more an object of enquiry amongst naturalists than pathologists. Dr. Hunter has remarked, as Hartmann, Tyson, and Pallas had done before, that hydatids taken from a sheep (the *cysticercus tenuicollis*) even twelve and fourteen hours after the animal had been killed, moved briskly with a kind of peristaltic motion over the whole body, on immersion in hot water; and Sir Everard Home states that in a similar experiment made by himself, he witnessed a very evident contraction and relaxation of their bodies, with a brisk undulation of the circumambient fluid, which continued for half an hour, and exactly resembled the action of muscles in more perfect animals.* The author last named submitted animalcules of the same kind to examination with microscopical glasses of a high magnifying power, but was unable to detect any appearance of muscular structure: he remarked, however, that their coats resembled paper made upon a wire frame, and, as this structure does not belong to membranes in general, considered it to be the organization upon which their motions depend.†

Observations are wholly wanting as to the particular effects on the human body of those hydatids already described, and stated to have been occasionally found in it; but it is probable that their morbid agency must nearly correspond to that of any foreign body situated in the same cavity or structure. During life, unless when they are evacuated either naturally or artificially, there appear to be no means of ascertaining that their particular presence is the cause of, constitutional disorder, even though, as when they occur within the cranium, it may be severe and irremediable. Under such circumstances therapeutic attention can be directed only on general principles to the relief of sympathetic disorder, and to the maintenance, as far as possible, of the due functions of the abdominal viscera.

Some of the inferior animals, particularly sheep, often become the subjects of disease in which the *H. cysticerci* are generated. A cachectic state of the body followed by abdominal dropsy, commonly described under the vague and indefinite term *rot*, are the conditions with which their occurrence is most usually observed. Co-existent with them are frequently found pervading the liver and in its ducts great numbers of the flat vesicular worm named *fluke*, *fasciola hepatica*: the small intestines are at the same time blackish, and easily lacerable, and the glands of the mesen-

* Croonian Lect. Lond. 1795.

† Ibid.

tery enlarged and indurated; purulent tubercles and cysts containing transparent fluid are also observed to pervade the lungs. Hydatids of the same kind are apt also to be generated within the crania of these animals, giving rise to that singular affection commonly called gid or staggers, from the particular effect produced on their locomotive powers: their precise situation in this cavity has been frequently discovered by the effects produced on particular nerves and the action of those parts under their influence, indications which have sometimes led to their extraction, to the perfect relief of the suffering animals. Wet seasons, variable temperatures, and watery pasturage, are the causes to which the occurrence of rot in sheep, and consequently hydatids, are usually attributed; and Dr. Jenner has proved, by direct experiments made upon rabbits, that the same animalcules could be produced at will by feeding them solely on green succulent food.* The production of hydatids in these instances is probably consequent to the general disease induced in the constitution, and its restoration to a healthy state in sheep is often successfully attempted by removing them to a dry and sheltered pasturage, with the exhibition at the same time of muriate of soda, considered the safest and most effectual of all the remedies of this distemper. To relieve the hydropic state of the body which accompanies it, diuretics are given, and it is from their diuretic action, we presume, that fox-glove and spirits of turpentine have been much extolled. Broom, heather, elecampane, and coltsfoot are also popular; and tonic medicines, such as the preparations of iron, have been highly recommended by those who have had the care of sheep thus diseased. How far medicines of the same kind may be useful in the human subject under circumstances apparently similar, we shall not pretend to determine; but direct experience having failed to supply the requisite information, some hints of practical advantage may be derived from analogy.

The second division of our subject refers to one distinct kind of hydatid which very commonly occurs in the human body, and is a simple bladder more or less transparent, without any visible fibres or other traces in its organization of animalcular life. It has been considered, however, from some phenomena presently to be noticed, of the same nature as the hydatids already described, and has been classed with them under a name proposed by Laennec, viz., *hydatid acephalocystis*, derived from the Greek words *α, priv.* κεφαλή, *caput*, and κύστις, *vesica*.

The shape of the acephalocyst is uniformly round or oval, and in size they vary from the smallest perceptible through every gradation to that of several inches in circumference. Their coats are translucent and composed of a white semi-opaque pulpy matter, separable into two layers of variable thickness in the same as well as in different specimens. The fluid they contain

is clear and transparent like water, but occasionally of a yellowish or amber hue; but their most distinguishing characteristics are, that they are always found unattached to each other or to the cyst in which they are included, together with a fluid very variable in its nature, sometimes consisting of serum, at others of serum mixed with blood, or pus, or both; occasionally of pus only, and now and then of a fluid which has the appearance of dirty water with chalk diffused through it; and it is remarkable that, whatever it may be, it does not affect the contents of the acephalocysts, a fact which has been considered indicative of an assimilative function proper to their tunics, and hence to favour the hypothesis of their animalcular nature. The acephalocyst is sometimes solitary, but in most instances a great number of them are found in the same cyst or sac: the latter is usually of a firm texture, formed of condensed cellular membrane, and consisting of two laminæ, the outer of which is strongest and thickest; the inner tender, soft, and pulpy; but together they have a strong contractile power, and have been observed on incision forcibly to protrude their contents. These sacs are sometimes fibrous in their texture, fibro-cartilaginous, cartilaginous, and even occasionally osseous. When acephalocysts, immediately after removal from the body, have been partially divided with a knife, the cut edges have been observed to be immediately incurvated, a circumstance which has been considered indicative of animal contractility. Adhering to the inner surface of a small proportion of them, several minute vesicles are to be seen, which have the appearance of so many pearls or studs; but examined with a microscope, they were noticed by Hunter to be merely sessile on the tunic, and to be covered by a thin transparent membrane, so as to be interposed as it were between the two. These he considered to be young hydatids, an opinion which Laennec amongst other pathologists also entertains; and that the numerous vesicles, observable with a microscope diffused throughout the fluid of acephalocysts, are of the same nature. They have been noticed in every variety of size, from the two-hundredth part of an inch in diameter to that of a red globule of blood, and even less; and the coats of the largest to be a little rough, with numerous filaments or villi, which, examined with a deeper magnifier, presented somewhat of a mulberry appearance. "It is not improbable," says Hunter, "that the small globules attach themselves by the villi to the side of the hydatid and to each other, and thereby give the appearance of being covered by a thin membrane. However that may be, the globules being found of various sizes floating in the liquor, seems to prove that they are originally formed there, and not in the coats of the hydatid upon which they are afterwards deposited."

To proceed with the graphic description of the same writer: "The hydatids in their growth and decay appear to pass through various stages; they are first found floating in

* See Inquiry into the Nature of tuberculated Accretions. By John Barton, M.D. 8vo. 1819, p. 96.

the fluid that fills the hydatid, and afterwards attached to its coats. The hydatid thus pregnant with young, if the expression may be allowed, adheres to the neighbouring parts, increases in size, and becomes itself a sac, containing numerous small hydatids. These after a certain time decay, and the skins or empty bags are squeezed together into a substance like isinglass. It is probable they still undergo a further change; two small bodies of the size of a common bean, of a cheese-like consistence, and covered with a skin, were taken notice of adhering to the bladder near its neck," in a human subject, in whom the bodies now described were found between the rectum and the organ just mentioned. "It may be a question whether those were not the remains of hydatids; but that must be determined by future observations. It is to be observed that the young hydatids are found in two very different stages; in the one they are attached to the coats of an hydatid that floats loose in the parent bag or sac; in the other extremely small globules adhere slightly to the inner surface of a bag or sac, which is firmly attached to the neighbouring parts, and covered with a strong outer coat. It is obvious that the progress of growth is very unequal in these two, and, indeed, inverted; for in the first the young ones are as large as the heads of pins, while the parent bag is not larger than a walnut, and floats unattached; but, on the contrary, in the second there is a large sac, with a strong outer coat, and a more tender inner one, adhering strongly to the surrounding parts, while the young ones that are very slightly attached to its sides are not of a larger diameter than a two hundredth part of an inch." Besides the small transparent vesicles already described, Laennec has remarked that on the exterior as well as interior surfaces of acephalocysts, some small prominences (*bourgeons*) of irregular form and variable size are presented to notice. These, we presume, correspond to the mulberry appearance adverted to by Hunter, and are considered by the former distinguished pathologist as nascent hydatids, which in a certain state of growth are detached, the interior increasing the number in the fluid of the acephalocyst, and those from the outside forming so many distinct and separate hydatids in the surrounding fluid. In some instances hydatids (probably of this kind) are stated to have been included in succession to the number of three or four, with the fluid proper to them interposed between the several layers, the last being distended in the usual manner of single hydatids. An illustrative specimen in a state of transformation, that appeared in the examination of a human body which came under his notice, has been described by Dr. Baron; at least such is our inference from the statement that its section exhibited a series of concentric laminæ, resembling very much the appearance of a urinary calculus.* Another instance of the same kind is related by Sir Astley Cooper in his valuable work on Diseases of the Breast,

page 41. Their appearance is thus described: when opened, they were found to be composed of numerous lamellæ, like the crystalline humour of the eye, or like the layers in the onion, which could be readily peeled from each other.

Acephalocysts have been found in almost every structure and cavity of the human body, but particularly in the liver, the uterus, the kidneys, and cellular tissue; they have been ejected in considerable numbers from the stomach by vomiting, and downwards from the intestines; brought up from the lungs by coughing, voided with the urine, and discharged from tumours in various parts of the body. Pallas seems to allude to their occurrence in the lungs and liver of the ox tribe and other ruminating animals, and Laennec has noticed their presence in sheep.

From the period of Tyson's publication already alluded to, it has been a question which refers particularly to the hydatids we are now considering, whether they are distinct members of the animal kingdom. We have cited pathologists of the highest repute who have supported this hypothesis, and it must be acknowledged that it has obtained an extensive credit; it behoves us, however, to examine the ground on which it is founded, believing, as we have reason to do, that the greatest misconception exists as to the nature of these bodies. Our knowledge of the structure of the acephalocyst has afforded no inference favourable to the conclusion, nor can we recognize any evidence of it in the retraction which is said to take place in its cut edges when divided, such being a phenomenon of mere organic life, and their incurvation an effect which would be mechanically caused in any spherical membranous bag distended with fluid under similar circumstances. Proof has been further sought, but found wanting, on the immersion of acephalocysts in hot water, no contraction having been evinced in obedience to this stimulus, which, as already stated, has occurred most obviously when the *H. cysticerci* have been the subjects of the same experiment. Baillie* and Monro,† as well as Hunter,‡ contend that this failure in the anticipated result may depend on the hydatids (acephalocysts) having been allowed to remain a longer time in the dead body before examination than would be compatible with their vitality, supposing them to be possessed of it; Dr. Monro has also stated that purulent matter proves fatal to hydatids, but if applied to acephalocysts, the assertion involves a *petitio principii* unsupported by facts. It must be admitted that there are phenomena in their economy difficult to be accounted for, from which arguments in favour of their animalcular nature have been advanced: these we shall mention seriatim. 1. Their original production; 2. their growth and increase, without any vascular continuation with surrounding structures; 3. the unvarying identity of their fluid contents under the diver-

* See Dr. Baron's Inquiry, p. 95.

sified media of that by which they are found surrounded; lastly, their inclusion, or, as it has been termed, the generation, of others often found in considerable numbers and different sizes within them.

The earliest hypothesis which appears to us to refer to the origin of the particular kind of hydatids now under discussion, ascribes their formation to an altered state of the lymphatics, suggested probably by a resemblance of the fluid proper to them to the usual contents of these bodies. It was supposed that on any accidental impediment to the transit of the lymph, the valvular structure of these vessels would prevent its reflux, and necessarily occasion a distention of its parietes between the obstructed portion and the valve immediately above it; and that, from their natural approximation to each other, a successive distention would ensue, giving rise to an adhesive apposition, or to a complete separation of them in the spherical form of the hydatids now called acephalocysts. This view of their formation seems to have originated with the celebrated anatomist Bartholine, afterwards to have been disseminated by Wharton and Nuck, and to have been generally adopted until their promotion, on the score of analogy, from the rank of inanimate to that of animated bodies.

If it be admitted that acephalocysts are animalcules, their origin must necessarily be involved in all the obscurity which envelopes the subject of generation in the lowest grade of insects, rendered still more incomprehensible by their natural localities in the bodies of men as well as of the inferior animals, unless, indeed, it be accounted for by the following general explanation, given us by Andral, which, to say the least, deserves considerate attention: "Besides the clot of extravasated blood which, by the experiments of Hunter and Home, has been proved susceptible of organization, it not unfrequently happens," says Andral, "that under the influence of causes more or less appreciable, the fibrine, either alone or accompanied with a considerable proportion of colouring matter, abandons the blood, and escaping from the vessels by some morbid process, finds its way into the adjacent tissues, as is proved to demonstration in the cavities lined by serous membranes. The fluid containing these is not unfrequently found to exhibit certain fibrinous concretions presenting evident marks of incipient organization; and of the same nature, though in a more advanced stage, may the transparent cysts now under discussion be considered, the formation taking place just in the same manner as the coagulum of fibrine, at first an amorphous mass, becomes vascular and organized." As successive links in the chain are placed "the cysticerci and other hydatids in their progressively complicated forms, and next to these the flattened worms, in which the characters of animal life become much better marked, by the manifestation of unequivocal movements, and by the appearance of different organs as distinct and as well formed as those of the vertebrated animals. In this way we pass by regular and almost insensible

gradations from the simple clot of fibrine deposited in a serous cavity, to the strongylus or the ascaris lumbricoides; just as during the formation of the embryo we observe it gradually advancing from the state in which it exists as a homogeneous mass, devoid of form or texture, until it acquires all the organs of a perfect animal; and as in the series of animated nature we can trace the development and progress of life and organization from the green matter of vegetables up to man. It appears to me perfectly futile to attempt fixing the point in this series of transformations where what is called animal life commences. If we give the name of animal to the cyst which floats loose in a serous cavity, and is moreover provided with vessels, and if we consent to admit the animal existence of this clot of fibrine, where are we to stop, or where draw the line of demarcation? If we admit to the rank of animal every aggregate of matter which, being developed in the interior of a being endowed with life, is capable of supporting itself, and of increasing in size without having any connexion with that being, the serous cysts already described must then be considered as animals, and accordingly they have been described as such by Laennec. But if we only recognize as animals those bodies which present some trace of sensibility or mobility, these cysts then forfeit all claims to that title; so that, in fact, this much agitated question turns out to be a mere dispute of words, which can never be finally adjusted until the contending parties shall agree in their definition of what it is which essentially constitutes an animal."*

The growth of the acephalocyst, it is evident, depends on some property inherent in its membranous portion, whereby it is fitted to appropriate to itself from the surrounding medium the particular fluid proper to it. The process appears to be analogous to that of secretion in serous membranes; but in the latter it must be remembered that red blood is the immediate pabulum of the secretions, whereas in the present instance it is a fluid which has already been eliminated from it; a circumstance certainly favourable to the hypothesis of the parasitic nature of acephalocysts, but which nevertheless may be referred to the mechanical process of imbibition, a property belonging, there can be little doubt, to the serous as well as other membranes of animal bodies.

The third division of our subject embraces the simple pellucid vesicles commonly called false hydatids, which are found either partially or wholly in contact with the adjacent tissues, and are supplied directly through them with the fluid by which they are sustained and their growths increased. As they have been usually adverted to in medical writings, they consist either of perfect bladders, capable of being detached without lesion of structure, or else are, as it were, diverticula from the sub-jacent membranous expansions, from which they could not be separated at their bases with-

* Vide Treatise on Pathol. Anat. Transl. vol. i. p. 477.

out laceration of a part essential to the integrity of one or the other. The manner in which the former are produced is a question yet undetermined, but the following explanation seems to us to be consistent with the knowledge we possess on the subject: that under particular conditions of the system, either general or local, there takes place a deposition of serous fluid, which accumulates in proportion to the distensible nature of the part; but according as the latter is more resistant, an increase of pressure ensues, serving to condense the surrounding cellular membrane into a corresponding envelope, and thus to present an entire cyst. Bichat, however, contends that the formation of the cyst takes place prior to the deposit of the fluid, which, though scanty at first, increases with its growth, and that it is first developed in the filamentous tissue, according to laws analogous to those of the growth of parts in general, to be referred, in his view, to unknown aberrations or unnatural application of those laws. He argues thus against the explanation previously advanced: "1. That cysts are analogous in all respects to serous membranes, and should therefore have the same origin; 2. that the mechanical hypothesis of their origin, in which all the vessels ought to be obliterated, does not accord with the exhaling and absorbing function of cysts, nor with the mode of inflammation; 3. that if these sacs are formed by the mutual application and agglutination or adhesion of cells, (that is, of the filaments,) the contiguous tissue ought to be diminished, or to disappear when they are bulky, which is not observed to take place; 4. that if cysts are formed by condensation of the filamentous tissue, and if their fluid is effused by exhalation, this fluid ought to exist in the organ which separates them from the blood."*

The second kind are produced by the distention of the interstices of the particular structures or of natural cavities with effused deposits of fluid, and vary, therefore, in nature, according to the texture of the parts in which they are situated, the quality of the fluid being determined anterior to its separation from its depositing vessels. It is, we presume, to cysts of this kind, under the denomination of hydatids, that Boerhaave and Haller have ascribed an origin in the follicles of glandular structures; which Monro has treated of as an alteration of the cellular membrane; and in like manner Portal and Broussais as the result of a chronic inflammation of the capillaries which convey the blood deprived of its colouring matter to the cellular membrane interposed between the serous and other textures. Single cysts of this kind are sometimes met with, but frequently they grow in clusters, and resemble bunches of grapes; sometimes they are thickly set on a broad surface, and present a honey-comb appearance; occasionally they are found adhering to each other at their sides, and when crowded on the superficies of an

organ having a cavity, or when produced in the same manner from the internal surface of another cyst, they occasionally lose their organic vitality in consequence of pressure at their pedunculated extremities. When single, they sometimes have broad bases, not unlike the vesications produced by a blister plaster, or boiling water, which might with as much reason be called hydatids as the cysts to which we now refer. The contents of these cysts as to quantity vary in every gradation from a single drop even to several pints of fluid, and are found also to differ in nature, being frequently clear, like water, often resembling serum mixed with blood, and occasionally purulent. To cysts of this kind recent pathologists have applied the term *hydroma*. Examples of it are often found in the female ovary, in which they vary much in size, and also in the colour and consistence of their contents from mere serum, with more or less of albumen, to reddish, bloody, or even tar-like fluid. Their appearance, it is probable, may depend on an altered condition of a particular part, as they have been frequently witnessed in bodies free from disease; but they are often the result of a hydropic state, which is general, when they appear to be produced under circumstances precisely corresponding to those of dropsy. Hence from an early period after the discovery of the lymphatics, their occurrence has been attributed to a morbid condition of this system of vessels; and though the links in the chain of their causes have never been distinctly traced, experience seems to prove that a cachectic state most commonly predisposes to their formation. Although frequently connected with disease which is irremediable, they are in themselves void of all malignant tendency; and their influential action on the organic functions seems to be limited to the degree of pressure occasioned by their presence and the nature of the organ in which they are situated.

An hypothesis has been promulgated by Dr. Baron, that the hydatid or vesicular form is the primitive state of the tuberculous and other morbid formations, as the strumous, scirrhus, sarcomatous, steatomatous, and fungous. The period at which these transformations take place he states is very uncertain; that they may commence in a few days after the hydatid is brought into existence, or that they may not occur at all, the original structure continuing for many years. The occasional co-existence of hydatids with such morbid changes is consistent with general observation, and is confirmed by the undoubted testimony of several pathologists cited by Dr. Baron. Proof, however, is wanting, that the one state is commonly consequent to the other; and supposing the elementary particles of such morbid growths to be deposited in a state of fluidity, we see no reason why they should be regarded as hydatids. On the same principles we conceive, might every globule of blood or every collection of fluid be similarly classed, and thus the real nature of the product be lost sight of in the extension of a term already too

* Elements of Pathol. Anat. by David Craigie, M.D. 8vo. edit. p. 52.

vague and indefinite. Moreover it seems very improbable that morbid products arising under a diversity of constitutional circumstances, and manifested by appearances as well as producing effects as different, should at any intermediate stage evince a perfect identity of character.

To Dr. Baron's work, however, we refer for the full elucidation of his views, which could not be transferred to this place without obliging us unreasonably to exceed the necessary limits of this article; and we do so with the less reluctance, because, whatever may be the reader's conclusion, he cannot fail to benefit by the consideration of the facts and reasoning with which Dr. Baron has supported his positions.

It has been already stated that hydatids have been found in most of the structures of the human body;* we shall now proceed to the practical consideration of them according to their several localities.

Hydatids in the brain.—The presence of animalcular hydatids in the human brain has been rarely noticed, but the occurrence of cysts under this denomination has been very frequently referred to by medical writers. Their real nature it is impossible to determine during life, but their effects are found to be similar to those from any other foreign bodies in the same structures, passing on from those of nervous irritations to the partial impediment and abolition of the functions of the parts under their influence, and ultimately in most instances, it is to be feared, to death.

An instructive illustration has been given to us by Dr. Abercrombie in the following case submitted to him by Mr. Headington:—A boy, aged eleven, was suddenly attacked

with dimness of sight, amounting to blindness. It went off in a few minutes; but from that time his sight was gradually impaired, and after a year nearly lost. He then had an affection resembling chorea, and after a short time suffered an attack in which he lay speechless for three days. This was followed by hemiplegia of the right side. He complained much of his head, which appeared to his friends to enlarge, and he sometimes lost his speech for two or three days. His intellect was not affected, but at times extremely acute. He died, after coma of five weeks continuance, about a year after the attack of hemiplegia, and two years from the commencement of the disease.

Dissection.—On the surface of the left hemisphere, the membranes adhered firmly to the surface of the brain for some extent on the middle lobe. On raising them at this place fluid escaped in great quantity, and on further examination it was found to have been discharged from the cyst of an immense *hydatid*, which was seated in the left lateral ventricle, and had gradually advanced to the circumference of the brain. It contained about sixteen ounces of limpid fluid, and besides these there were several ounces in the proper cavity of the ventricle.*

In an examination of the brain of a man who died on the fifteenth day of synochus, we discovered not long since a pellucid cyst, full of transparent, yellowish, limpid fluid, lying close to the base of the brain at the side of the tuber annulare. Its size was that of a plover's egg, but during life there were no particular symptoms to indicate the presence of such a body. It would be to little purpose to go on enumerating similar instances of morbid formation. We refer, therefore, to the several works on general pathology, especially to those of Bonetus and Morgagni, and to the very valuable work entitled *Elements of Pathology*, recently published by Dr. Craigie, in which (page 477) references are given to several remarkable instances of similar encysted bodies found within the cavity of the cranium, and imbedded in the substance or cavities of the brain.

It is obvious that medical treatment under such circumstances must be limited to the relief of the organ oppressed, and to the suitable regulation of the functions of those which, primarily influenced by external agents, exert a corresponding action upon it. The means of effecting these objects could not be defined for general application, even if the cause of the existent disease were ascertained; but latent as it must be, alleviation of the consequent symptoms can be rationally attempted only by a reference to the general principles of therapeutics.

Hydatids in the thorax.—The lungs, though not often the nidus of hydatids, have occasionally been found to contain them; and instances are related of acephalocysts having

* Experiments on the nature of the fluid constituent of hydatids have not been sufficiently numerous and diversified to determine how far our knowledge of the subject may be advanced by the aid of chemistry. Dr. Marcet, in "an account of various dropical fluids" (*Med. Chir. Trans.* vol. ii. p. 373.) has thus described his analysis. "A quantity of this fluid was procured from a hydatid attached to the kidney of a woman, whose body was opened by Mr. Cooper and myself at Guy's Hospital. It was clear and transparent, though of a yellowish colour. No coagulum or turbidness appeared on adding dilute sulphuric or muriatic acid, but concentrated muriatic acid produced a milkiness. Infusion of galls and oxy muriate of mercury occasioned precipitates. Heat did not produce any coagulation except after very considerable concentration. The specific gravity of this fluid was not ascertained, but a thousand grains of it being evaporated to dryness, at a temperature not exceeding 180°, the residue weighed thirty-six grains, and yielded by incineration a saline mass weighing 8.7 grains. This saline mass contained the usual ingredients; namely, muriate of soda crystallized chiefly in octohedrons, phosphate of iron and of lime, and a small portion of sulphuric acid. Upon the whole, this fluid, which was examined long since, and with much less minuteness than the other, appears to resemble much in its chemical composition that of hydrocephalus and spina bifida, only containing a larger proportion of animal matter, which appeared to be chiefly of the muco-extractive kind, since it did not coagulate by heat or gelatinize by cold or concentration."

* *Researches on the Pathology of the Brain*, by John Abercrombie, M.D. Part iv. Case 29.

been ejected from this organ by coughing. Their presence usually excites considerable irritation, and gives rise to cough, pain, dyspnoea, and quickness of pulse; but we are unacquainted with any particular symptoms by which their existence here could be positively ascertained. A case in which their expulsion from the lungs was followed by complete recovery has been recorded by Dr. Doubleday, in the fifth volume of the *Medical Observations and Enquiries*, by a Society of Physicians in London, 1779, and another by Dr. Monro, unattended with any pulmonary symptoms except that of pain on the right side of the chest behind the mamma, and which was not relieved by bleeding or the application of a blister. In this particular instance there was no sense of oppression nor difficulty of breathing, nor any alteration in the state of the pulse, and the patient could sleep on either side or on his back. By coughing he was relieved of portions of hydatids, and also of some entire, varying from the size of a hazel to that of a walnut, and in quantities amounting at times to as much as would fill a pint measure. The larger hydatids contained a fluid which was clear and viscid; in the smaller it was of a yellow hue and reported to have been bitter to the taste. A few days before their ejection the patient suffered very acute pain in the breast, which he compared to that of the penetration of a pointed instrument. The previous fits of coughing were violent and attended with paroxysms threatening suffocation, which continued for two or three minutes. These effects were first manifested when the patient was fourteen years of age, and occurred at intervals for seventeen years, when at length he was attended by the present Dr. Monro and his father. Having been recommended to smoke tobacco and to inhale the fumes as deep as he could into the chest, the symptoms appeared to be arrested, and for the following eight years he was known to have remained free from any return of the disorder.*

Instances are on record of hydatids having occasionally passed through morbid perforations in the diaphragm into the thorax. In the first volume of the *London Medical Communications*, we read an account of a post-mortem examination in which "a common cyst found to contain a quantity of them, and attached to the liver, omentum, mesentery, and peritoneum, passed through a perforation in the diaphragm; from thence expanding again, it adhered to the pleura and mediastinum, filled almost the whole of the left cavity of the thorax, and communicated in several places with the lungs, which were ulcerated. Had the patient lived long enough, it is possible that hydatids would have been coughed up, as one of the openings from the cyst into the lungs was large enough to admit a goose-quill." In the substance of the liver, which weighed sixteen pounds and a half, another large cyst

was found. A similar case is related in the *Edinburgh Medical and Surgical Journal*, vol. ii. p. 170, in which "an immense cyst occupying the whole cavity of the abdomen" was found after death connected to the mesentery. It was distended to the utmost, and contained thirty-five pints of hydatids, many of them exceeding the largest oranges in size. In both these cases the disease was supposed to be common ascites during life, and in both a fruitless attempt was made to draw off the fluid by tapping. An instance somewhat analogous has been recorded by Dr. Collet,* in which hydatids, originally lodged within the liver, were discharged by coughing: the patient, a female aged thirty-seven, "first complained of lowness of spirits and of an oppression on her breath," followed by some œdema of the ankles, which, however, soon disappeared. A violent cough, attended with great dyspnoea, and the occasional expectoration of tough viscid phlegm, soon followed, and the subsequent ejection by coughing of hydatids at different periods in the course of six months, amounting to the number of one hundred and thirty-five: these varied from the size of a pea to that of a pullet's egg, and were in their ruptured state, no water either accompanying or following them: there had been a swelling at the umbilicus evidently containing fluid, and distention of the whole abdomen, which in parts communicated to the hand of the examiner the sensation of lumps; these, however, had disappeared, and the case promised a favourable issue. Another instance of the same kind is related in the *London Medical Journal*, vol. vi. p. 593, 1785. A lady, during an illness, which continued more or less for three years, "coughed up several hundreds of hydatids, most of which were burst, and of these many must have been as large as a pullet's egg: those which were not burst were only about the size of a nutmeg. This patient was considered dropsical, and to have disease of the liver: she, however, recovered her health.

It is probable that the bronchi are very rarely if ever the original seat of hydatids, but that they are passed into their ramifications from the parenchyma of the lungs and the pleura, or from other structures, as in the cases above related; but, under whatever circumstances, we may generally anticipate recovery if their expulsion through this channel has commenced, provided that other disease be not co-existent, when of course the probabilities of the issue must depend on the nature and circumstances of the latter, and the remedial means be applied accordingly.

"Although," says Andral, "instances are not uncommon of animalculæ having been found in the vascular system of quadrupeds, I know only of a single occurrence of this nature in the human body." The subject was examined by himself at La Charité. "I found

* See *Morbid Anatomy of the Human Gullet*, by Alexander Monro, M.D. 8vo. edit. 1811. p. 279.

* *Transactions of the College of Physicians*, Lond. vol. ii.

both lungs," he writes, "filled with hydatids, and thought that these *entozoaires* were lodged in the parenchyma of the lungs; but a more close examination disclosed the existence of hydatids in the pulmonary veins of both lungs. They had all the characters of accephalocysts. Around them the pulmonary tissue was in some places sound and crepitating; in others obstructed and hepatized. An hydatiferous cyst, with cartilaginous parietes as large as an orange, existed in the middle of the liver, and contained from eight to ten hydatids. The individual who was the subject of this case was fifty-five years of age, for a year previously had been ill-fed, and often experienced considerable distress. The symptoms of an aneurism of the aorta under which he laboured were the object of therapeutic attention during life; and from the post-mortem examination, the latter appeared to be the effect of impeded circulation, consequent to the presence of hydatids in the pulmonary veins."*

Hydatids in the abdomen.—Hydatids have been frequently found in the several viscera of the abdomen, occasionally attached to the peritoneum, and sometimes loose, either between it and the abdominal muscles, or amongst the viscera themselves.

Except the kidneys, the liver is more frequently affected with hydatids than any other organ, and in sheep as well as in some other quadrupeds under the particular circumstances of wet seasons and marshy pasturage, this appearance of disease is apt to prevail very extensively. In the human species corresponding causes have not been observed to influence their formation, although there is reason to believe that a cachectic state of body has been conducive to it. Symptoms of a disordered liver to a greater or less extent are usually present; occasionally the same effect is produced as when a calculus is passing through the gall-ducts, viz. violent spasmodic pain at the epigastrium, frequent vomiting, with an unaccelerated pulse, and sometimes jaundice alternating with intervals of good health.

When hydatids are confined within the substance of the liver, there appear to be no means of ascertaining their existence; but when formed on its outer surface near its lower edge, it is probable that they may be detected by examination. When, however, the parietes of the abdomen are thick, and hydatids or their cysts not distinct, but lying in contact with each other and making an irregular tumour, it will hardly be possible to form an accurate opinion of their nature. If the tumour be gradually formed, and the general health little affected, it is probable that hydatids may be the cause. Close attention to the sensation which the tumour yields on pressure or on striking it gently with the hand, may also assist in enabling the examiner to form a probable idea as to its nature. If it should con-

sist of hydatids, it will generally feel to a certain degree soft; and if the hydatids should be very large, there may be an obscure sense of fluctuation on striking the tumour with one hand while the other is applied to the opposite side of it. If, moreover, it should occupy a great part of the cavity of the abdomen, and can be clearly traced from the liver as the source of its growth, there can be little doubt of hydatids being the cause.*

Some instances have already been referred to in which hydatids had passed through a perforation in the diaphragm from the abdomen, and were ejected by coughing from the lungs: they have occasionally also been evacuated from abscesses, and sometimes from the abdomen with the fluid discharged by tapping; in the former most frequently to the complete relief of the patient. The circumstances under which they thus occur being variable, preclude any specific character being given of them, and therefore must be illustrated by example. A female was treated with mercury under the supposition that hepatitis and consequent suppuration in the liver had taken place. In about ten days the mercury began to affect her mouth, and at the same time she voided an incredible quantity of the *tæniæ hydatigenæ*, or hydatids, by stool and vomiting, calculated by her attendants to amount to a thousand, varying in size from that of a small pea to an inch and a half in diameter. An hepatic abscess afterwards opened externally, a gall-stone was discharged from it, and she ultimately recovered.†

An instructive case of the same kind is related by Mr. Gaitskell, of Rotherhithe, in the fourth volume of the London Medical Repository. The patient, a married female aged thirty-eight, had been under treatment for hepatic disorder with inflammatory symptoms, and, a short time after pytalism was induced, began to void biliary calculi, which in three months amounted to forty-seven in number, and with them hydatids not less than a thousand, varying from the size of a grape to that of a peach. At the date of the report the patient was convalescent.

An example of fatality occasioned by a sac of hydatids situated in the porta of the liver, which by its pressure on the vessels produced complete obstruction and jaundice, is related by Dr. Duncan, Sen. in the Edinburgh Medical and Surgical Journal, vol. iv. p. 137.

Hydatids which are ejected from the stomach or discharged from the alvine canal, have in most instances been generated in the liver, but occasionally it is probable that they have passed from their common sac in consequence of its adhesions to, and resulting communication with, some part of this tube: they may be transferred in the same manner, we conceive, from the other abdominal viscera, but having found an exit through this channel,

* Andral's Pathol. Anat. Trans. vol. ii. p. 424; and Med. Repos. vol. xix. p. 347.

* See Works of Mathew Baillie, M.D. vol. ii. p. 212.

† Lond. Med. Journ. vol. x. p. 7. 1789.

recovery so commonly ensues that the opportunity of proving the truth of the remark by ocular inspection can rarely occur, nor can we adduce any such positive testimony in support of it.

From the co-existent disease, rather than from the presence of hydatids in the liver, the judgment of the practitioner must be formed as to the issue; and the requisite treatment of the patient must necessarily be influenced by the same circumstances. The hepatic disorder will generally be such as to render the exhibition of mercury necessary, and the stimulating effect of this remedy on the absorbent system renders its use, at all events externally, of considerable importance in the removal of hydatids, whether situated in the liver or in any other of the abdominal viscera.

The presence of hydatids in the spleen is an occurrence which has not often been noticed: during life the symptoms occasioned by them in this organ are too obscure to be recognized, and can never become the specific object of medical treatment. We shall subjoin a remarkable case of this kind in preference to any discussion which we cannot find on experience.

"A labourer, thirty years of age, of a phlegmatic habit, after lifting a heavy load, complained of pain in the chest, accompanied with cough and much debility. Two months afterwards his legs began to swell; he spat blood twice, a little at a time, which degenerated into a purulent expectoration of a bitter taste. He now applied for medical assistance, under the idea of his disorder being the first stage of a pulmonary consumption. His pectoral sufferings abated, but the œdema increased, and the parts became erysipelatous, but soon changed their colour again on the application of dry aromatic fomentations; and the œdema subsiding on using twice antihydrotic medicines, the patient thought himself cured. A short time after, however, when he had been at hard labour, the spitting of blood returned, and he complained of stitching pains in the chest; the scrotum was swelled, the pulse very slow, and digestion disturbed. These symptoms were also attended with headach. The pectoral sufferings were again soon removed, but the dropsical swelling remained, and a painful, hard, circumscribed tumour, beginning in the left hypochondrium, and extending upwards to the xiphoid cartilage, now made its appearance, which, with the obstinacy of the dropsical swelling, induced Dr. R. to make use of drastic medicines. An abscess now formed over the right knee, which effused a considerable deal of ichor; but the dropsy increased, and the patient at last died suddenly after a long ambiguous state of health.

"*Dissection.*—The greatest mark of disease was found in the spleen, which was unusually distended, and weighed about nine pounds; and a tendinous place was found in its centre, about the size of a hand, from which, on being

cut open, a great quantity of water escaped, with a number of globular vesicles, varying in size from that of a millet-grain to that of a duck-egg, containing partly a clear liquid and partly a friable substance, which by the help of a magnifying glass exhibited other small vesicles. Many of them were burst asunder and dried away. The bag containing these bladders divided the disorganized spleen into two halves, formed by an aponeurotic membrane, from half a line to two lines in thickness, interwoven with the substance of the viscus, and furnished with very swollen blood-vessels. It ran obliquely through the spleen, so that its larger half lay to the left and upwards, and the smaller to the right and downwards. All the other viscera were healthy, except that some water was contained in cavities caused by serous membranes."*

The pancreas is still more rarely the seat of hydatids than the spleen, and it is probable that their occurrence in this organ can only be ascertained by post-mortem examination.

Of the various organs of the body, the kidneys are more frequently than any other affected with hydatids; these for the most part are simple cysts produced in their peritoneal covering, and on inspection present an appearance resembling bunches of grapes: they may exist to a very considerable extent without manifesting any distinguishing characteristics of their presence during life, and without at all affecting the quantity or sensible qualities of the urine. Sometimes, however, though rarely, acephalocysts have been found to pervade these organs, but no particular symptoms have been evinced to render their presence recognizable during life. Pain is commonly felt in the loins during their formation; there has also been remarked symptomatic fever, nausea, and vomiting, but these are symptoms which belong also to other diseases: they have occasionally, however, been passed through the urethra, and in such instances have sometimes occasioned dysuria from interruption to the passage of the urine, either in the ureters, the neck of the bladder, or in some part of the urethra.†

One or more acephalocysts having been passed with the urine, a continuance or repetition of the precursory symptoms, or the subsequent occurrence of dysuria, will be almost certain indications that others are in their transit; and even if the same symptoms should have been caused by the passage of renal calculi in a subject prone to the latter formation, the treatment during the paroxysm consequent to the obstruction will alike be directed to the relief of an organic channel thrown into a state of spastic contraction in consequence of unnatural distention. The symptoms of acephalocysts in these as in other organs will be variously modified by other disease with which they are almost always connected, particularly,

* Lond. Med. Repos. vol. vi. 1816, p. 332. Extracted from Horn's Journal, 1815.

† Works of Mathew Baillie, M.D. vol. ii. p. 257.

and most frequently perhaps, abscesses following blows or other injuries. On this account, therefore, it seems to us that examples are essential to an intelligible description of the morbid states in which their presence is evinced. We subjoin the following as particularly illustrative of renal acephalocysts.

"A gentleman, aged 32, was thrown from his horse in February 1780, by which he received an injury on the loins, and had considerable hematuria in consequence. After the first fortnight he experienced no further inconvenience until the June following, when he complained of cough attended with bloody expectoration, which he ascribed to the previous accident; but from a little attention he recovered, nor experienced any symptom of his late disorder until about three years afterwards. In December 1783, he was attacked with rigour, and felt a return of severe pain in the loins, extending to the region of the left kidney: in a few days he perceived an enlargement in the hypochondrium, which continued gradually increasing until the latter end of February 1784, a space of nine weeks: after the first month, the tumour was so little painful that the patient was enabled to travel to London, a distance of one hundred and thirty miles, to consult Dr Lettsom, by whom the case is detailed. Upon examination the tumour, which was as large as an "infant's head," was found to contain fluid: it extended from the vertebræ of the back along the left *hypochondrium* to the umbilical region, and occupied the whole space from the ribs to the *os innominatum*. The pain increased with the swelling, and was aggravated by exercise or motion, but was relieved by an anodyne, "till at length some difficulty of making water came on, and for many hours a total obstruction: in this situation surgeons of the first eminence were consulted, to determine how far it would be advisable to make an incision in the side and perforate the cyst, in order to take off the pressure on the bladder, and obviate the fatal event which the retention of urine threatened: this was on the 20th of February; the result was, that, from the uncertainty of the situation of the tumour with respect to the intestines, which were suspected to take a curve over its anterior surface, as well as from the risk of exposing such parts to the external air, the operation was protracted, and the usual opiate of the patient was ordered to be increased in the evening, which was the chief remedy besides the use of cicuta and anodyne clysters. He passed a painful night, suffering frequent and violent rigors, but early in the morning experienced the most happy relief by a discharge of a large quantity of thick pus with the urine, which was followed the next day by that of pus and numerous hydatids.

"In a few days the tumour subsided, and the purulent discharge ceased; after this he continued recruiting in strength for nearly a fortnight, when his side enlarged again after exercise in a coach, probably by a large hydatid

stopping up the ureter; rigors and strangury succeeded as before, and the tumour became as large as in the first instance, till the latter end of March, when he experienced a second discharge in every respect like the former, except that the hydatids were much larger. His health and strength again returned, until his side filled a third time after exercise on horseback, and continued swelling until the 25th of April, when he was again relieved by a third discharge of hydatids, and these were considerably larger than those of the preceding attack. The passages now became so open that he frequently discharged the hydatids, after walking or riding, without enlargement or pain of side; or, if he felt uneasy, or perceived a tendency to tumescence, by pressing his hand upon the side he could squeeze them into the bladder, where they would remain some time before they were discharged; but the hydatids became at length so considerable in size that it was with great difficulty they passed the urethra. The last that he voided was on the 12th day of July, which was so very large that it stopped up the urethra, and remained in it for a considerable time, until the weight of the accumulated urine forced its way. The earliest hydatids burst in their exit; they gradually increased in magnitude in every successive discharge, the first being not larger than a pea, and the last about the size of a pullet's egg. After the last-mentioned discharge his health gradually recovered, and the patient enjoyed, without the least inconvenience, the chase and every other species of exercise as well as ever he did.

"During the whole progress and termination of the disease very little medicine was administered, except cicuta, gum arabic, clysters, and anodynes. He once took an emetic when the tumour became uneasy, previous to the second discharge, and which seemed to hasten the eruption of hydatids. Bark was tried, but with manifest inconvenience, between the eruptions, and was left off. After the last discharge it seemed beneficial, as well as asses' milk."*

From the history of the disease there remains very little doubt but that it originated in the kidney, where the suppuration was extended to an amazing degree, till at length the pus, breaking through the cyst in which it was contained, passed into the ureter, and was thereby conveyed into the bladder.

A temperate man had been for some years subject to paroxysms of pain in the region of the right kidney, which appeared to descend in the course of the ureter of the same side, and ceased after discharging by the urethra some membranous bags (acephalocysts) of different sizes, some whole, but others broken and empty; there were considerable intervals between the paroxysms, during which the patient enjoyed perfect health; but the latter, from recurring every four or five months, had now increased in frequency, and the hydatids in size.

* Memoirs of the Medical Society of London, vol. ii. p. 33. 1789.

The patient had suffered thus for ten years previous to the date of the above report, but at first their discharge was attended with a sense of weight or pressure rather than of pain, preceded sometimes with slight rigors. These discharges, together with purulent matter, at length recurred as often as five times within a twelvemonth, accompanied with increasing pain preceded by a sense of fulness in the region of the right kidney; for three years there was a cessation of the above symptoms reasonably attributed to continued attention for four months to the following prescription of Dr. Lettsom:—

R Extr. cicutæ et pilulæ sapon. aa ʒi. fiant pil. xxiv. cap. ii. omni nocte.

R Elect. lenitiv. ʒi.

Æthiop. mineral. ʒʒ.

Syrupi simpl. q. s. ut fiat elect. de quo cap. magn. nucis mosch. prout venter postulat verit.

R Uvæ ursi ʒiʒʒ. coque ex aq. font. ʒix ad ʒvi. sub finem coctionis addendo rad. glycyrrh. ʒʒ. et cola.

R Liq. colati ʒʒ.

Tinct. stomach. ʒi. fiat haustus bis per diem sumendus.

Three years having elapsed, the report states that after some considerable pain in the back, he voided again several more hydatids, of a longer size than formerly, to the basis of which, or that part which appeared to have been attached to the kidney, some sabulous matter adhered; he discharged several more at different periods, but had experienced such amendment from the use of the same prescription, the powder of uva ursi only having been substituted for the decoction, as to give a fair promise of perfect recovery.*

For another instructive case of the same kind, related by Dr. Alexander Russel, the reader is referred to the third volume of the Medical Observer and Enquirer, published by a Society of Physicians in London, 1767. In this instance the patient retained his health, though at intervals he discharged hydatids with his urine occasionally mixed with purulent matter and streaked with blood; these at first are stated to have been round, "of the size of a common garden pea, with a small stalk." The patient about ten years before, when at school, had experienced "some violent complaints in the urinary passages, when he voided dark coffee-coloured urine with great pain." Dr. Baillie has given us an account of the dissection of a case in which the right kidney of the body of a man who had been a soldier was converted into a bag, capable of containing at least three pints of fluid, full of hydatids (acephalocysts) differing from a pin's head in size to that of an orange, and only a small part of the kidney retained its natural structure.†

When hydatids have been passed into the bladder, irritation to a greater or less degree is excited to propel them with the urine, and it

is probable that the exceedingly thickened state of the parietes of this organ in those in whom they have existed has been occasioned by increase of action, as was suggested by Dr. Baillie in the above mentioned instance. In another related by Tyson the same effect was observed to have been produced: in the latter the cysts or sacs (acephalocysts) were twelve in number, varying from the size of a goose's to that of hen's eggs, and distended the bladder to the size of a child's head, though little or no urine was contained in it: the ureters are stated to have been impervious at their vesical extremities, but distended to the calibre of the intestines of a child, and at their renal extremities to the size of a hen's egg, the kidneys themselves being of their natural size and figure, but resembling rather large bags than fleshy substances: the cavity of the pelvis (whether of one or both kidneys is not stated) contained above three ounces of fluid. The liver, lungs, and heart of this individual were considerably diseased, and polypi were observed in the aorta and pulmonary vein.*

Hydatids have occasionally been found between the bladder and the rectum, as in the case already referred to, which came under the observation of Dr. Hunter,† and had occasioned only the particular symptoms of dysuria and distention of the abdomen: the patient, a man forty-six years of age, died suddenly, and on post-mortem examination the bladder was found to be enormously distended, reaching full eight inches above the pubis, its fundus having risen to within two inches of the arch of the colon; it contained between five and six pints of urine, and the hydatidous tumour was found between the neck of the bladder and rectum, completely filling the pelvis, and thrusting the former forwards and upwards.‡ It was remarked by Dr. Hunter that the prejudicial effects of the hydatids in this case were limited to those of mechanical pressure, and that of the numerous cases related by writers hardly any had proved fatal when an outlet for them was procured.

The peritoneum and its various duplicatures are occasionally the nidus of hydatids, i. e. of acephalocysts and those of the simple encysted kind, but rarely if ever without implication by disease of one or more of the subjacent viscera: it is probable that the development of the hydatids takes place under the different states of cachexy arising from a depressed condition of the vital powers, from the combined circumstances of constitutional diathesis and chronic disease, and not unfrequently are the consequence of inflammation of this membrane taking place under the same circumstances as ascites, with which they are commonly co-existent: the pathognomonic sym-

† Morbid Anatomy.

ptoms are thereby rendered extremely obscure, and there appear to be no other means of detecting this morbid process than by manual exploration of the abdomen, and thus only when there is an inequality in the surface, and a partial fluctuation can be perceived on altering the positions of the patient.

The constitutional symptoms complicated with those of the local disease are generally such as to betoken a fatal issue in the human subject, should the real nature of the distention of the abdomen from this cause be ascertained during life; but when the hydatiferous sac is situated between the peritoneum and muscular parietes, adhering to and distending the latter into a tumour, or in fact an abscess as most frequently happens, an artificial opening will be the principal means of relieving the patient; and if this be the only disease, a favourable issue may almost always be anticipated. A sense of unequal fluctuation communicated to the hand of the examiner will be the only method of distinguishing the general nature of this from other tumours; and if the fluid of the common cyst is purulent, it will have the common characteristics of an abscess, the presence of hydatids being concealed until the latter be emptied of its contents, as will generally be the case also, whatever may be the particular nature of the contained fluid. The same observations will apply also to any part of the muscular structure with which formations of this kind may be connected.

Cysts commonly denominated hydatids sometimes constitute the bulk of tumefied ovaria, and are probably formed by the progressive enlargement of the small vesicles which belong to their natural structure: they often acquire an immense size in this organ as well as in the uterus, and vary frequently in their construction, some of the larger cysts enveloping smaller ones, and thus resembling acephalocysts, with which they have not unfrequently been confounded. The inner, however, will be found to be reflected from the outer cysts, like the serous membranes when they are reflected off from the internal parietes of cavities upon the organs contained in them, and to receive from them a continuation of vascular structure; in this respect differing essentially from the isolated state of acephalocysts, and always sufficiently distinctive of the latter kind of vesicular bodies. Though there appears to be no reason why acephalocysts should not constitute ovarian disease, we are not aware of any instances of the kind being on record; and as the preceding morbid condition more properly belongs to ovarian dropsy, and will be discussed under that head, it is not requisite to enlarge upon it here; we have to notice, however, that the suspicion of such an instance in a female forty years of age, who had the symptoms of ovarian dropsy, but attended with more pain than is common in that disease, has been recorded by the present Dr. Monro as occurring within the observation of his father: about a fortnight after the patient had been seen by him, the tumour subsided in the night, and the patient told him "that she

had passed several watery stools with skins in them."*

Hydatids of the uterus constitute a morbid condition of this organ very frequently referred to in medical writings, but it is probable that they are invariably attached cysts, and never acephalocysts. They are described by Bailliet† as vesicles of a round or oval shape, with a narrow stalk to each, by which they adhere on the outside to one another. A large one has generally a number of small hydatids adhering to it by narrow processes, and in the same manner to the uterus by small filaments; and portions of a substance resembling blood and coagulating lymph are frequently mixed with them. A similar substance is attached to the internal part of the uterus, from which the footstalks of the hydatids grow. As these increase in number they distend the uterus in proportion, and at length by their quantity stimulate it to contract upon them. "The cause of this complaint has not been ascertained; it sometimes appears as a morbid condition of the opaque membranes of the ovum; and in such cases, interfering with its functions, it destroys the vitality of that body, and thus produces abortion.

"It is probable that the existence of pregnancy is not necessary for the production of this disease; and perhaps a morbid condition of organized coagulating lymph may, under certain circumstances, have the power of originating it, but what these circumstances are is not known. It may admit of a doubt whether, in consequence of a morbid condition of the ovary, some separation of the corpora Graffiani may not induce the complaint." Hydatids of the uterus, when arising from the destruction of an ovum, are preceded by the symptoms of pregnancy common to the period before this change takes place, and the time when it happens is marked by the breasts becoming flaccid, and the sickness and symptomatic effects of pregnancy going off; but of themselves they do not appear to produce any peculiar symptoms, with the exception of one to be mentioned hereafter. The greater number of inconveniences attending the disease arise out of the pressure made by the enlarged uterus upon the subjacent parts, such as retention of urine from compression of the urethra, constipation of the bowels from compression of the rectum, œdema, and cramp of the lower extremities. These symptoms, however, are not necessarily present, and instances have occurred in which they have been altogether wanting. When the pelvis can no longer contain the enlarged uterus, that viscus will rise into the abdomen, and may be felt as a circumscribed tumour through the parietes.

The function of menstruation is usually interrupted as in pregnancy: on examination the body of the uterus will be found enlarged, and suddenly bulging out from the upper part of the cervix. All these symptoms, however, attend other enlarged states of this organ; but

* *Morbid Anatomy of the Gullet, &c.* by Alexander Monro, M.D. 8vo. Edin. 1811, p. 273.

† *Morbid Anat.*

besides the absence of the movement of a foetus usually felt by a pregnant woman, the size of the belly and state of the womb rarely correspond with the supposed period of pregnancy, and from this condition as well as other diseases it is especially characterized by the discharge of an almost colourless watery fluid. "This watery discharge is to be distinguished from that which attends the cauliflower excrescence, by the irregularity and suddenness of its appearance and cessation; being produced by a rupture of one or more of the coats of these hydatids, in consequence of the occasional contraction of the uterus upon them, or of any sudden violence, as in the act of coughing or sneezing; whereas the discharge from the cauliflower excrescence being a secretion from its surface, is constantly escaping. It may be distinguished also from those splashes of urine which sometimes come away from pregnant women, by being wholly inodorous."

When the uterus is excited to contraction upon hydatids, the process resembles that of incipient labour, for which it has unfortunately been mistaken even by experienced practitioners: "the os uteri is dilated; the hydatids are expelled by periodical pains; and then for the first time danger presents itself in the form of alarming hemorrhage. This hemorrhage is more frightful than that which follows the removal of the placenta from an uncontracted uterus; and the reason is obvious—the placenta covered only a limited space of the internal surface of the uterus, whereas the hydatids spring from every portion of the cavity."* In some cases milk is secreted after the hydatids are expelled, and occasionally pain in the hypogastrium with febrile symptoms follow.

The uterus is sometimes distended by a single hydatid or cyst to an enormous size, but this variety is very rare, for the very experienced author above cited, to whose invaluable work we are most largely indebted for our information on this part of the subject, has stated that such an instance has never come under his observation, and concludes, from the accounts given of it, that its effects are purely mechanical. From the equality and size of the enlargement "it would be difficult to determine whether it were produced by a single hydatid, or by a deposit of solid matter in the substance of the uterus. The fluidity of the contents of the tumour does not necessarily cause a sensible fluctuation of these contents. A full bladder felt above the pubis does not give to the hand the sensation of a fluid being contained within it. The discharge of a watery fluid in large quantities is in this variety of the disease the first announcement of its existence and the presage of its speedy removal.

"The water having escaped, the cyst is expelled, and the disease terminated without the occurrence of those distressing symptoms which threaten the patient's life in the disease first described.

"This last variety being very uncommon,

the practitioner will hardly be prepared for its occurrence, and the patient expecting it to be of long continuance will be agreeably surprised by an expeditious and favourable termination of her complaints.

"Examination by the finger will enable the practitioner readily to distinguish the single hydatid from the more formidable disease, fleshy tubercle; a discrimination of importance in forming the necessary prognosis, though symptoms arising from both forms of disease demand similar modes of relief."

It is probable that distention of this organ by hydatids is the particular condition to which some writers have referred under the term *hydrops uteri*; for it seems impossible from its natural position with respect to its aperture and fundus, that any large accumulation of fluid could take place, and continue for a length of time in it, unless inclosed in a cyst. Such is the expressed opinion of the writer above cited, and that neither he nor Dr. Denman should have witnessed such an instance appears to us evidence almost conclusive.

The presence of a tumour consisting, as suspected, of a bag of hydatids situated between the neck of the uterus and the rectum, has occasionally been found to interfere considerably with the process of parturition, but the nature of its contents it would appear impossible precisely to determine either before or after delivery, unless an opportunity were afforded by a post-mortem examination. A tumour of this kind would occasion little pain in its growth other than that arising from pressure on the surrounding parts, the nature of which would materially depend on its size; but the greatest inconvenience would consist during pregnancy, by its adding to the mechanical impediment to the passage of urine.

As the occurrence of hydatids in the female breast, in the tunica vaginalis testis, the thyroid gland, and between the muscles and integuments, constitutes the morbid structure of local diseases especially belonging to surgery, their present discussion would be irrelevant to the particular objects of this work.

Having no reason to suppose that hydatids have any inherent malignancy, the variety of morbid actions resulting from their presence are to be ascribed to mechanical irritation and compression; these are seen to be modified by their size and number, their locality, and the predisposing circumstances of the constitution in which they may occur. As mechanical irritants, the effects they produce, whether inflammatory or spasmodic, must be treated entirely on general principles adapted to the age and habit of the patient, and other circumstances, either morbid or natural, under which their occurrence is observed. When a tendency has been evinced to their expulsion by natural processes, through either of the outlets of the alvine canal, art may take advantage of the suggestion thus afforded, and by an emetic or purgative, according to the operation already induced, expedite the accomplishment of the object to be effected. When they have had their seat in the chest, or have passed into this

* Observations on Diseases of Females, by Charles Mansfield Clarke, part ii. p. 116.

cavity from the abdomen, so as to be ejected through the lungs by coughing, nature may be allowed uninterruptedly to continue its purpose, but any morbid action that may result from the effort must be counteracted by the method of treatment its peculiarity may point out. When impacted in either of the biliary ducts, and giving rise to spasmodic pains and other symptoms resembling those which arise from biliary calculi similarly situated, an emetic, unless particular circumstances should contraindicate its use, ought to be given, and if its action fail to procure the relief desired, the same kind of treatment will be required as for the analogous condition just referred to, viz. a full dose of the tincture or wine of opium, or Battley's sedative, or tincture of henbane with compound spirit of sulphuric ether in camphor mixture, to be repeated or not according to its effects: if the bowels should be in a constipated state, a combination of castor-oil and laudanum may be preferred, or if great irritability of stomach should prevail, opium combined with calomel, or with calomel and compound extract of colocynth, may be advantageously substituted: a hot bath, a blister to the epigastrium, and injections per anum of hot water with laudanum, or, if need be, purgative injections, are remedies one or all of which may be had recourse to as the necessities of the case may indicate.

When a cyst within the abdomen, containing acephalocysts, can be detected, and is adherent to its muscular parietes, distending them and producing great disorder of the system, an artificial aperture will be the readiest and perhaps the only method of cure. If contained within an abscess, the latter will be the prominent object of consideration, and the evacuation of its contents may prove a cure to the patient, and give the earliest manifestation of their presence. If not acephalocysts, however, but the attached hydatids which grow as it were from the organic structures or tissues, the disease with which they are complicated will form the more prominent object of consideration: it will be obvious that any distention of the abdomen from this cause cannot be relieved, as in ascites, from tapping, an operation to which, in the want of other means of relieving a patient, a practitioner may be urged: should the hydatids be numerous, little relief could follow, and even if the evacuation of a large hydatid were to promise greater advantage, the too common issue of such cases should warn him, except under particularly advantageous circumstances, against a step by which his reputation might suffer, and the expectation of the patient be disappointed.

When it has been ascertained that the liver is affected with hydatids, the removal of the hepatic disorder which must at the same time exist, should be the prescriber's aim; and the process will comprehend the only rational method of relieving the organ and the rest of the system which sympathizes with it. It has been suggested that mercury in its various forms may possess a specific quality adapted to the destruction of the vitality of animalcules

hydatids, particularly acephalocysts; and on this principle has its use as well as that of some other medicines been resorted to when their presence has been recognised or suspected. How far the idea may be founded on fact, time and particular attention to the subject must determine, but experience has sufficiently shown that its influence in such cases of disease has been most salutary, and is indispensable to restoring the natural secretion of the liver, and thereby communicating to the whole of the assimilative organs that degree of vigour which is the main defence of the system against noxious influences from without and morbid depositions within the body, and still further to the removal of various products of disease which a contrary state has engendered. The specific stimulus also of mercury to the absorbents is an additional reason for its prescription when the more direct removal of hydatids cannot be effected, whether situated in the liver, spleen, pancreas, kidneys, peritoneum, or other structures.

When productive of great inconvenience from their situation between the rectum and bladder, or, as in pregnancies, between the vagina and the rectum, and the nature of the resulting tumour can fortunately be determined, an incision into its most prominent part it is probable will speedily and effectually relieve the patient. The circumstance, however, being rare, and the records of medicine affording no general guide for practice on this point, the writer feels it incumbent upon him to state that the above recommendation has been suggested by the perusal of a valuable paper on tumours within the pelvis occasioning difficult parturition, by Mr. Park of Liverpool, inserted in the second volume of the *Medico-Chirurgical Transactions*, p. 296, and particularly by a successful example of the practice therein recorded, and of another in which the tumour disappeared in consequence of the pressure occasioned by the act of parturition. If hydatids have been voided with the urine, and symptoms should arise indicative of the passage of more of these bodies from the kidneys to the bladder, relief should be sought by the immersion of the patient in a hot bath, and by the administration of antispasmodics, as advised for the corresponding effects produced by their impaction in the biliary ducts. If checked in their passage through the urethra, the impediment we conceive might easily be overcome by rupturing the enveloping bag with the point of a bougie. When the uterus has been the seat of hydatids, we are told by the highest authority that "all attempts to cure the disease artificially, and to arrest its progress otherwise than through the natural efforts of the organ, have been of no avail. The patient is to be informed of its nature, and the result is to be patiently waited for. As symptoms arise they are to be treated accordingly, and the practitioner will best perform his duty by watching over the complaint, and by doing no more than is absolutely required. But when the period arrives at which the uterus is excited by distention to unload itself of its contents, then all

his skill and energy will be wanting, and all his efforts will be called forth to control the hemorrhage and to sustain the powers of the constitution." "Two or three fingers or the whole hand should be covered with pomatum, and carefully introduced into the uterus, and carried up between its sides and the hydatids, which are to be detached from the part to which they adhere by the most gentle efforts. The mass being now included in the hand of the operator is to be brought out of the uterus, it being remembered, in the performance of this operation, that the degree to which the os uteri is dilatable without laceration is in proportion to the size of the whole uterus both in pregnancy as well as in this disease. So that, supposing it to be enlarged by hydatids to the size of the viscus in the sixth or seventh month of pregnancy, the whole hand may be, if necessary, introduced through the cervix; whereas, in smaller dimensions of the uterus, if any attempt is made to introduce it through the cervix, however carefully it may be attempted, a laceration of it may ensue, and thus the patient be involved in a new danger. The contents of the uterus having been naturally expelled or artificially removed, and the hemorrhage restrained, the strength is to be restored by allowing the patient a nutritive diet, and by the exhibition of such medicines as tend to increase the tone of the system, amongst which the mineral acids and preparations of cinchona may be accounted the most serviceable: these or other medicines, possessing similar properties, should be from time to time exhibited until the vigour of the system shall have been entirely restored.

"The usual cautions given to women after delivery should be here impressed upon the patient, such as confinement to the horizontal posture until the parts shall have acquired their usual size and tone."^{*}

"The acknowledged efficacy of the ergot of rye in stimulating the pregnant uterus to contraction suggests the idea that it may in the same manner be administered with advantage as soon as it is known that the distention of the uterus is occasioned by hydatids: the writer, however, is not aware that it has ever been used under such circumstances, but as there is some reason to believe that it possesses to a considerable extent the additional property of restraining the hemorrhagic tendency of bleeding vessels, it appears probable that it may prove an eligible medicine for the purpose above specified."[†]

* See Observations on Diseases of Females, by C. M. Clarke, M.R.C.S. &c. part ii. p. 120. Lond. 1821.

† "In the fourth number of the Glasgow Medical Journal, Dr. Macfarlane, in his observations on *polypus* of the uterus, gives a case where the ergot appeared to act by promoting the expulsion of the polypus. One drachm was infused in four ounces of water, and one ounce given every two hours. The whole was given before the effect was produced. In the course of a few hours the tumour was discovered to be in the vagina. Four days after the exhibition of the ergot the polypus fell off."—From Dr. Young's Observations on the Use of *Secale Cor-*

The single hydatid of the uterus by its growth effects its own cure, and thus affords a hint which may, under other circumstances of the disease, be usefully applied; when arrived at a considerable size, a rupture of it suddenly takes place, its fluid escapes, and the cyst is expelled; the patient being in a moment relieved of her sufferings and the cause of her fears, in most instances requiring nothing more than a bandage round the abdomen to give support to the organ which has so long been distended and consequently relaxed.

In all cases of hydatids the condition of the body and the specific nature of the coexistent disease, be it either predisponent or consequent, must be special objects of remedial attention; hence the treatment connected with these morbid formations involves also that of cachexia, of the various disorders of the digestive organs, of dropsy, &c. each of which having a proper place in this work, it is necessary only to refer to them here; and it would be further a waste of time to dwell on means to be adopted for the removal of a morbid deposit under circumstances in which its presence could only be discovered by post-mortem examination.

Abstractedly considered, the removal of hydatids may be contemplated by three different methods: first, by their direct expulsion from the body, either naturally or artificially, as already explained; secondly, when their expulsion cannot reasonably be anticipated, by reinvigorating the relaxed habit of the body, and thus communicating to the absorbent system its lost power, an indication which will also be required to be attended to for the prevention of their recurrence when already got rid of; thirdly, by exciting the absorbents to extraordinary action, when the exercise of their natural function is inadequate to the end in view.

To reinvigorate the relaxed habit of body it will be necessary to avoid the influence of the external causes by which it has been reduced to this state; to select a dry and healthy residence; to use a nutritious diet adapted to the powers of the organs of digestion, improving the condition of the latter by promoting, in the first place, the due secretion of the liver, by the exhibition of such of the preparations of mercury and to such an extent as the occasion may demand. The irritative fever induced by such disorder having been allayed, the tone of the stomach must be invigorated by corresponding medicines, as, for instance, by some of the preparations of cinchona, especially the sulphate of quinine, or by quassia, rhubarb, gentian, or cascarrilla, combined either with the alkalies or sulphuric acid, according to the condition of the stomach and alimentary canal: the preparations of iron and sulphate of zinc are also medicines which will generally be adapted to constitutions thus affected.

When these or similar means are found unavailing, and the inconvenience resulting from the presence of hydatids is so considerable as

to render it expedient to attempt their removal by exciting the absorbents to extraordinary exertion, a process which requires more discrimination and care perhaps than any other in medicine, it will be necessary either to have recourse to the free use of mercury in one or other of its forms, or by persevering in the use of evacuates of the alvine canal or kidneys, or by maintaining a continued state of nausea with repeated doses of tartrate of antimony to effect the same end; but of all the excitants of the absorbent system none appear to have so direct and powerful an influence upon it as iodine: we have, however, no experience of its use in disease resulting from hydatids, and rest our anticipations of its efficacy in such cases on the great advantage stated to have been derived from it in scrofula as well as from the particular actions observed to have been produced by it in the treatment of this disease.*

In the article BRONCHOCELE will be found an excellent account of the medicine in question, which renders it unnecessary for us to enter into any further discussion upon it here; we shall, therefore, merely state, as the result of our own experience of iodine and the hydriodate of potash, that the evidence of their effects on the system in medicinal doses becomes very gradually perceptible, but that these remain so long after their use has been discontinued, as to be prejudicial by their excess, and, as far as we know, the means have not been discovered for regulating them when the necessity has been indicated.

(William Kerr.)

HYDROCEPHALUS, from *ὑδωρ*, water, and *κεφαλή*, the head. Under this term was formerly comprehended every preternatural effusion of serous fluid in the region of the head, whether external to the cranium or contained within it. In process of time, however, it became limited to effusion occurring within the cavity of the skull. Systematic writers have laid it down that such effusion may take place either between the cranium and dura mater, into the great cavity of the arachnoid, in the subarachnoid cellular membrane, or finally into the cavity of the ventricles. But hydrocephalus, in the more limited sense in which it is usually understood in this country, means a serous effusion taking place into the ventricles, or (which is a much rarer occurrence) into the sac of the arachnoid.

The disease is divisible into acute and chronic. Hufeland, Coindet, and many other late writers, have restricted the use of the name hydrocephalus to the chronic effusion, and have employed the term *hydrencephalus* to designate the acute variety; a species of nomenclature which is objectionable, as it proceeds on the erroneous assumption that the water in the latter case, and in it only, is always confined within the cavities of the brain.

1. **ACUTE HYDROCEPHALUS**.—This species has been defined by Cullen—a disease which

affects chiefly infants and young persons under the age of puberty, arising gradually, and manifesting itself at first by lassitude, feverishness, and pain in the head, and subsequently by slowness of the pulse, dilatation of the pupil, and somnolence. In addition to several of the above symptoms, Hufeland (*Conspectus Morborum—Hydrencephalon*) has noticed in his definition the tendency to convulsions and paralysis, vomiting, and constipation.

Though the chronic species is plainly alluded to by several of the older writers, it has usually been supposed that the symptoms of the acute had, till the beginning of the last century, when it was imperfectly described by Petit, escaped the observation of practitioners. This, however, is a mistake, as Hippocrates was certainly acquainted with it, as appears from a passage in the treatise *De Morbis* (lib. ii. cap. 6.), where he distinctly notices this species of water in the brain, and says that it gives rise to acute headach, pain in the eyes, double vision, blindness, vomiting, and fever;—thus clearly enumerating some of the most characteristic features of the disease, whilst at the same time he recommends purgatives, emetics, and erethines, as the means best suited for its removal.

The first accurate account of acute hydrocephalus which appeared, was that by Dr. Whytt, in a posthumous work published in 1768, entitled *Observations on the Dropsy of the Brain*. His history of the symptoms and progress of the affection is so full and accurate, that a late French writer asserts that little of any importance has been since added to it. So much cannot, however, be said for his hypothesis as to the nature of the disease. He considered it a kind of passive dropsy, and all its symptoms merely the effect of the pressure made on the brain by the effused fluid. The disposition to vomit is attributed to the sympathy of the stomach with the brain; the slow, irregular pulse of the second stage, to the cardiac nerves receiving an imperfect supply of nervous energy; the quick pulse of the third stage, to the injury now done to the cerebral fibres, and the irritation thence arising in the whole system; and, finally, the dilatation of the pupil and stertorous breathing, to the compression of the brain. But neither his theory of this affection, nor his despondence as to the possibility of its ever being cured, have been justified by later and more extensive observation. Dr. Fothergill's remarks on the hydrocephalus internus, and Dr. Watson's observations on the same subject, appeared soon after, and the latter contained one of the first instances on record where the disease terminated in recovery. A valuable addition to the usual mode of treatment was made known in 1775 by Dr. Dobson, who, with a view to increasing the activity of the absorbents in the brain, was led to the employment of mercury, and had the satisfaction to find it successful. The first approach to a correct theory of the disease was contained in the thesis of Dr. Quin, of Dublin, published in 1799, in which he pointed out its affinity to the inflammatory

* Lugol on Iodine, by Dr. O'Shaughnessy. 1832.

diseases, and supported his views by a reference to the appearances which are found on dissection in those who have fallen victims to it. This manner of considering the disorder necessarily led to a great improvement in the mode of treating it. A similar view of hydrocephalus was taken about the same time by Dr. Rush of Philadelphia, who believed it to be closely allied to phrenitis, and pushed the antiphlogistic method of treating it still further than Quin had done. Dr. Withering held a similar opinion as to its inflammatory nature, and, like Quin and Rush, considered the effluvia here, as in many other instances, a mere result of inflammation, and not as constituting the essence of the disease. His introduction of digitalis into its treatment likewise entitles him to a place in the literary history of this affection. Dr. Percival of Manchester strongly advocated the use of calomel and opium in hydrocephalus, and strove to give precision to the mode of employing the various remedies previously in use. Amongst the writers who have most contributed to throw light on the nature and treatment of hydrocephalus, we may place, in addition to those already mentioned, the names of Cheyne and Abercrombie in this country; Odier and Coindet in Geneva; Guersent and Lallemand in France; Formey, Portenschlag, and above all Gölis in Germany. Besides these, we shall have occasion to allude, in the course of this article, to several others who have made important additions to our knowledge of the disease.

Precursory symptoms.—In a great majority of cases premonitory symptoms may be detected; and of these the greater number and the most striking are connected with derangement of the digestive organs. The appetite is either capricious or defective; the tongue slightly furred and the breath heavy; the epigastrium and hypochondria are occasionally tumid and tender on pressure; the biliary secretion is deficient or vitiated, as is evident from the torpor and irregularity of the bowels, and the unnatural appearance of the stools; the urine is high-coloured and diminished in quantity; the cutaneous circulation loses much of its vigour, as is evident from the faded and unhealthy complexion and harshness of the skin. To the attentive observer slight indications of the derangement of the cerebral functions may even at this early period be discovered, in the languid manner and frequent drowsiness; the disturbed and restless sleep, from which the child awakens unrefreshed; in the occasional complaints of giddiness or confusion, of noise or slight pain in the head, or of pains like those of rheumatism in various parts of the body and limbs. The pulse as yet deviates little from its natural condition, but on attentive examination some of its beats are found weaker than others, and an occasional intermission may sometimes be detected. The child becomes silent and irritable, indifferent to such persons and things as it formerly took an interest in, frequently assumes a grave and thoughtful appearance, or falls into a reverie, from which it

awakens with a sigh. Notwithstanding all this evidence of deranged function, the patient often makes little complaint, even when closely questioned. When the disease is about to manifest itself in a more unquestionable shape, flushings and chills frequently alternate; the gait becomes laborious and unsteady. "In stepping forward," says Gölis, "they raise the foot as if they were stepping over a threshold—they totter and stagger as if drunk."

Dr. Yeats, who has made the earlier stages of the disease his peculiar study, places amongst the premonitory symptoms occasionally present, tenderness in the scalp, stiffness of the neck, increased sensibility of the eyes to light, and in some rare cases severe ear-ach. He also draws attention to the remarkable change from the healthy appearance which the countenance undergoes, the transient paleness and occasional collapse of the features, the dulness and loss of expression in the eyes, and the dark line under them. A teasing cough is sometimes present; there is an unusual tendency to constipation. If aperient medicines be given, the consequent evacuations are both harder and less abundant than they were wont to be from a similar dose; in colour they are sometimes lighter than natural, and at others tinged of a dark greenish hue, and accompanied with slimy matter.

It must be confessed that there is nothing essentially characteristic in the above symptoms, and that even when all are taken together, they rather indicate a derangement in the functions generally, than point in an unequivocal manner to incipient disease of the brain. Still they are sufficient to justify much watchfulness on the part of the friends and of the medical attendant, and particularly so when the child discovers an unusual precocity of intellect, or is one of a family which has already suffered from hydrocephalus, or from scrofula in any of its forms. The mere occasional exhibition of a purgative will in such cases, as Dr. Yeats very truly observes, usually prove quite inadequate to the removal of the symptoms; nothing less than the systematic employment of a combination of alteratives and aperients, continued for some time, being capable of producing this effect.

Dr. Cheyne has the merit of having been one of the first writers who strongly directed the attention of the profession to the derangement in the functions of the liver and of the alimentary canal, which so often precedes, and not unfrequently seems to excite, this affection of the brain. The proportion of cases in which the diseased action commences in the abdominal viscera is, he thinks, very considerable. He was led to this belief partly by having observed how usually derangement of the above named organs precedes hydrocephalus, and partly from the remarkable benefit which, in the early stages of the affection, so often ensues upon the use of active purgatives, and finally, from the frequency with which unequivocal marks of disease are discovered in the liver or intestines on dissection. In the incipient stage, or while the disease of the brain

is as yet only forming, the colour of the stools indicates an inactive state of the liver, whilst at a subsequent period, when hydrocephalus has become fully established, the bile seems to be both vitiated and in excess. The intimate sympathy which exists between the brain and the liver is well known to surgeons, and that between the brain and the stomach and intestines is familiar to every one.

There is, we think, a general aversion amongst French pathologists to admit the sympathetic or secondary origin of diseases, and accordingly most of them, in treating of hydrocephalus, have looked upon the morbid appearances found in the abdomen as a mere casual complication, and by no means the cause of the cerebral affection. M. Brachet of Lyons has, however, departed from the general rule, and admitted a gastric variety of hydrocephalus (*hydrocephalite gastrique*), in which the disorder of the digestive organs evidently precedes that of the brain, and in which subsequently, during the progress of the cerebral affection, the violence of the gastric symptoms seems clearly to indicate that the irritability of the stomach is not the mere effect of sympathy, but the result of inflammation in the mucous membrane itself.

Less importance has been attributed by Dr. Abercrombie than by most other late British writers, to derangement of the chylipoietic viscera as a cause of hydrocephalus. Disease of the brain in unhealthy children, he admits, may appear in connection with that of the liver or other abdominal organs; but the latter, he thinks, cannot correctly be said to be the cause of the former; on the contrary, he looks upon both as a common result of a tendency to chronic or scrofulous inflammation. When we consider, however, the close and unquestionable sympathy which exists between the head and the digestive organs, and take along with this the greater exposure of the latter to irritating causes and consequent functional derangement, we are disposed to think that the now very generally received opinion as to the frequent origin of hydrocephalus in abdominal disorder is well founded. Dr. Abercrombie, indeed, himself admits that the more acute affections of the bowels have some pretensions to be considered an occasional cause of the disease, though even here the connection is, he thinks, very obscure; and the secondary affection in some of them arises, perhaps, merely out of the general febrile excitement. In admitting the precedence of the derangement of the digestive organs and its occasional connexion with disease of the brain, all that is of any practical importance is conceded. How this connexion is to be explained matters little. The comatose state in which inflammation of the mucous membrane of the bowels in infants about the period of weaning often terminates, is a striking instance of this origin of cerebral derangement. A remarkable diminution of the urinary secretion frequently precedes the oppression of the brain, and may possibly sometimes, as Dr. Abercrombie has suggested, be in some degree connected with it.

Under the title of "Erethysm or Irritation of the Brain in infants," Dr. Whittock Nichol has described a state which, as it is accompanied by no increased determination of blood to the head, is distinct from inflammation, though it may, if neglected, terminate in it. It seems, consequently, to be one of the forms in which the precursory symptoms of hydrocephalus occasionally present themselves, and in which they appear to depend on a peculiarly irritable state of the nervous system. "It is a state," says Dr. Nichol, "in which inordinate effects arise from ordinary impressions upon different parts of the nervous system." The child is wakeful, irritable, and attentive to every sound and every object of sight, and is easily startled; the eye is very sensible to light; there is frequent sneezing; and repeated winking or a firm spasmodic closing of the eyes is occasionally observed. A frequent, sudden cry, without any obvious cause; clenching of the fist, with the thumb laid across the palm; throwing back of the head, and a degree of opisthotonos, are amongst its occasional symptoms. The temperature and pulse may be sometimes raised, but are for the most part natural. Scrofulous children are the most prone to this affection. It may be called into existence by any irritation of the extremities of the nerves, as by painful dentition, by disorder of the liver or alimentary canal, by surgical operations, ulcers, burns, or suppressed discharges. Great wakefulness in infants should always excite attention, as it is very apt to terminate in inflammation of the brain. Children in whom this alarming symptom appears should be carried out much in the open air, and have the head sponged daily with cold water, and the bowels kept in a free state. If it still persist, and we can detect any evidence of undue determination of blood to the head, leeches must be employed. If, on the other hand, the watchfulness and increased sensibility of the nervous system exist simply, small doses of Dover's powder are recommended by Dr. Nichol, and should be repeated at intervals of five or six hours, so as to procure a sufficiency of sleep. We believe, however, that when the bowels are duly attended to, and care is taken to give the child the advantage of air and exercise, the aid of narcotics need rarely be had recourse to; and till every other method of inducing sleep has been tried and failed, we should certainly not advise their exhibition.

Though hydrocephalus in its advanced stages presents considerable uniformity in its symptoms, yet so great a variety is there in its manner of commencement, as fully to justify Quin in styling it a truly proteiform affection. These varieties have been reduced by Dr. Cheyne to three principal ones, which may be respectively entitled the gradual, the rapid or violent, and the secondary, under one or other of which most of the cases met with in practice are reducible.*

First or gradual form of attack.—It is

* Hopfengärtner has made a division of hydrocephalus into three varieties, which coincides very nearly with that of Cheyne, viz, into, 1st, the *nervous*, which at its commencement strongly resem-

in this form that the precursory symptoms, into which we have entered with so much detail, are the most obvious. The disease here comes on by slow degrees, and at its commencement its true nature is involved in considerable obscurity. The child is indisposed for many days or even weeks, complaining from time to time of slight pain in the head or belly, together with which there is anorexia or capricious appetite, and evident derangement in the functions of the abdominal viscera. It is all this while somewhat feverish and dispirited; its colour fades, and the eye becomes dim. A dragging of one of the legs, or a painful stiffness in the back of the neck, has sometimes been observed from the very commencement. The pain in the head soon becomes severe, returns at shorter intervals, and is complicated with vomiting, which, as well as the headach, is much aggravated by motion. By these symptoms the fears of the friends are at length awakened. The child now seems unable to support the weight of the head, sighs frequently, and looks dejected; the eyes are pained by a strong light, the pupils much contracted, and flashes of light are occasionally complained of. The derangement of the abdominal functions is indicated by the white tongue, by costiveness, or the unnatural appearance of the stools, which are at first of a clay colour, but gradually become gelatinous and of a dark-green hue, and have a peculiar heavy smell. The pulse becomes rapid, and frequent exacerbations take place, characterized by increased heat and irritability, with flying pains in various parts of the body, in the nape of the neck or limbs, the chest or abdomen. This first stage usually lasts for ten days or a fortnight, the patient gradually becoming weaker and much altered in appearance, unsteady in his motions, and fretful.

Second or rapid form of attack.—The disease here assumes a more acute and turbulent form. After a brief period of indisposition, which has possibly been overlooked, the fever appears suddenly and violently, with only short and irregular intermissions. There are frequent flushings, severe headach, occasional brilliancy of the eye, with increased sensibility of the retina, and indeed of the whole nervous system, and frequently pain in the abdomen, and tenderness on pressure.

It is this form of hydrocephalus which bears so strong a resemblance to fever as often to have been confounded with it. With proper care they may, however, be usually distinguished. "We are led to suspect," says Cheyne, "some deeply seated evil from the frantic screams and complaints of the head and belly, alternating with stupor, or rather lowness and unwillingness to be roused; and we are struck with the great irritability of the stomach, which exists in a degree beyond what we generally find it in the fevers of this country, retching and vomiting being brought on by a

bles a low nervous fever: 2d, the *inflammatory*, characterized by high fever and evident congestion of the head: 3d, that which succeeds to *scarlatina* several days or weeks after the disappearance of the eruption.

change of posture, and certainly by every attempt to sit up in bed; and the disordered state of the bowels which attends this irritability of the stomach is also remarkable. And when at any time the child has a little respite from the violence of these symptoms, we find our suspicions confirmed by his look; for when the features do not express pain or terror, there is not unfrequently a vacancy of look, the eyes being set, with an expression of dejection which is peculiar to certain diseases of the brain."

Third form of attack.—When hydrocephalus supervenes upon other diseases, as upon scrofula or painful dentition, the exanthemata, remittent fever, or hooping-cough, it is called metastatic or secondary. When it ensues in the course of an acute disease, its approach is most insidious. The symptoms of the early stage are almost all absent, and palsy and convulsions often afford the first evidence of the brain having become implicated. Even pain in the head is occasionally never complained of; and Dr. Quin alludes to a case in which not one characteristic symptom of hydrocephalus had occurred, and yet a large quantity of fluid was discovered in the ventricles.

Of these three modes of commencement, the first is the most frequent. The second occurs perhaps seldom more than either of the other two, but is the most regular in its progress, and presents the different stages the most distinctly marked. It answers to what Gölis has called the *tumultuous* form of hydrocephalus; and to Guersent's *hydrocephale ataxique*. It is the most acute variety, and Gölis thinks it the most amenable to the influence of medicine, both because it occurs in the healthiest children, and because, being often ushered in by sudden fever and severe convulsions, it is apt to excite attention in its commencement, and thus has more frequently the benefit of early treatment. But if the critical moment for the employment of active measures be lost, in a few days, or sometimes even in a few hours, effusion and palsy ensue. Recoveries from the third form are very rare, which is ascribed partly to the progress which the affection of the brain has usually made before there is any suspicion of its existence, and partly to the debility produced by the previous disease often rendering active treatment inadmissible.

Stages of hydrocephalus.—The great variety and complexity of the symptoms of hydrocephalus have led most writers on the subject to attempt their simplification by distributing them into separate groups characteristic of successive periods of the disease. Dr. Whytt, struck by the remarkable differences which the pulse presents in the progress of this affection, has assumed it as the groundwork of a division into three stages, in the first of which the pulse is quick, in the second slow and irregular, whilst in the third it rises again, and becomes rapid and feeble. By Gölis four stages have been described, founded on the presumed pathological condition of the brain at successive periods of the disorder. These are, first, the period of turgescence,

which answers nearly to what we have called the precursory symptoms; second, the period of inflammation; third, that of effusion; and, lastly, that of palsy. But two stages, on the other hand, have been admitted by Frank and by Conradi; what Gölis calls the stage of turgescence being by them considered as merely indicative of the approach of the disease, whilst the two last stages of Gölis and of Whytt, not appearing to them to be really distinct, have been consolidated into one. The threefold division of Whytt appears, however, to have practical advantages sufficient to justify us in retaining it. It is that which has been adopted by Cheyne in his valuable essay; but in naming these stages, he has proceeded on a different principle from Whytt, characterizing them by the state of the nervous system instead of that of the circulation. Thus, the first he calls the period of increased sensibility, the second that of diminished sensibility, and the third that of palsy or convulsions. "In the first stage," says he, "every stimulus produces an impression more than proportioned to its common effects. There is generally a great aversion to light and to sounds; there is watching, sickness, pain, and a quick pulse. In the second stage, the child is not easily roused, his pupil is dilated, his pulse slow; he is lethargic, with obstinately costive bowels. In the third stage, which perhaps might be considered as a continuation of the second, there is squinting, rolling of the head, raving, stupor, convulsions, with a rapid thready pulse."

Many cases do, it must be confessed, present themselves which set these and all other artificial divisions at defiance, cases in which the most careful observers fail in detecting any thing like a succession of regular stages. Thus convulsions, in place of first occurring near the end, occasionally usher in the disease; and as to the pulse, we have ourselves found it keep high during the whole course of the illness; whilst others have met with cases where it never exceeded the natural standard; and others, again, instances of its being remarkably slow at the very commencement of the attack.

First stage.—The morbid phenomena of this period are so variable, that it would perhaps be impossible to give any description of it answering accurately to all cases. Amongst the symptoms most frequently present are pain in the head and eyes, occasionally alternating with pain in the abdomen, in the limbs, or in the nape of the neck. There is usually a certain degree of fever, with great restlessness and total inability to sit up for any length of time. During the sleep, which is very disturbed, there is frequent grinding of the teeth, and the child often awakens with a scream of terror. The head feels hotter than natural, the conjunctiva is occasionally slightly injected, and the pupil usually closely contracted. There is a manifest aversion to light and noise, with other indications of increased sensibility of the nervous system. The intellect is often but little impaired, for replies, though unwillingly made, are usually correct. The symptoms of disorder in the digestive organs are numerous.

The nostrils are always dry, and the lips cracked. The tongue is for the most part slightly furred, and the breath has a faint sickly smell. There is usually complete anorexia, but often less thirst than would seem consistent with the degree of feverishness present. Vomiting very frequently occurs, and is aggravated extremely by the erect posture, or by carrying the child out of bed. The epigastrium and hypochondria are often tumid and slightly tender on pressure, but in the progress of the disease the belly usually falls in, and becomes flaccid, though no proportional increase in the stools has taken place. There is commonly a great tendency to constipation; and evacuations, when procured by medicines, are generally of a dark greenish spinach-like appearance. The occurrence of such discharges does not depend, as many persons have asserted, on the employment of calomel, as they often exist before a single dose of this medicine has been given, and are frequently procured also by other purgatives. We have not, however, by any means found them invariably present. Their peculiar colour has been attributed to morbid bile, but there is reason, as we shall afterwards see, to doubt whether this be universally the cause. The urine is deficient in quantity and turbid, with a whitish sediment; it is often retained or suppressed for a great many hours, and dysuria is not unfrequently complained of.

The functional derangement of the respiratory organs is manifested by the occasional cough, the irregular breathing and moaning, and by that deep sighing which is almost pathognomonic of affections of the head. The pulse is considerably accelerated, and is very excitable. An occasional irregularity and slight inequality in the force of succeeding strokes may be discovered as the second stage approaches. The skin is dry and of an unhealthy colour. An eruption of almost imperceptible vesicles, which become, however, more obvious towards the latter period of the disease, now occasionally manifests itself. They occur chiefly about the mouth, cheeks, and forehead, the outside of the humerus, and the upper part of the chest. They were first pointed out by Formey of Berlin, and have been subsequently noticed by Gölis, Raimann, Schmalz, and other German pathologists. Though these writers speak of this eruption as an almost invariable occurrence in hydrocephalus, it has attracted little attention in this country, where almost the only mention of it that we have met with is that by an anonymous writer in the second volume of the *Edinburgh Medical and Surgical Journal*, who says that it has been considered as a certain sign of approaching death. Whilst on the subject of the skin, we may mention that ecchymosed and gangrenous spots have been observed near the close of fatal cases, and we have at the same period remarked a few large-sized vesicles scattered over the body at distant intervals.

The duration of the first stage varies according to the acuteness of the attack, from a few hours to a week or more.

Second stage.—The pulse, which had been

gradually getting weaker, now becomes irregular, of unequal force, very variable, and unnaturally slow; yet it is still liable to be greatly accelerated on the slightest exertion, or when the patient is taken out of bed, or even placed in the sitting posture. The slow pulse is accompanied with a gradually increasing heaviness and torpor, and the head is now generally less complained of, though this is by no means universally the case. Squinting and impaired or double vision now occur along with dilatation and immobility of the pupil, an oscillatory state of the iris occasionally preceding its permanent retraction. The child lies with the eyes half closed, in a soporose state, which is interrupted from time to time by exclamations of suffering extorted by the momentary increase of pain. The sickness and vomiting often now diminish; appetite occasionally seems to return, the child greedily swallowing any food which is presented to it; but the bowels still continue obstinately bound, except while under the influence of powerful purgatives. The stools as well as the urine are passed unconsciously. The hands, which are tremulous and unsteady, are frequently raised to the head and back of the neck, and the child is almost incessantly picking at its nostrils, lips, or hair. Spasmodic winking or a fixed stare, a stern or a desponding expression, often rapidly succeed each other. There is great emaciation, and frequent partial suspirations indicative of extreme debility and of irregularity in the distribution of the blood.

The soporose state is now often suddenly and unexpectedly dispelled, the child recovering the use of its senses, and noticing and even taking an interest in surrounding objects. But this deceitful calm is usually of short duration, and is followed within one, or at most two days, by a deeper state of coma than before. The shrill piercing scream, which is so characteristic of hydrocephalus, occurs chiefly in this stage; and during its continuance the pulse becomes almost innumerable, and the cheeks suffused. The duration of the second stage may be variously stated at from one to two weeks.

Third stage.—A feeble attempt at reaction now manifests itself, the pulse again rising and attaining to a height which is scarcely equalled in any other disease. We have counted it as high as two hundred in a minute, and Whytt once found it even so high as two hundred and ten. Convulsions in every degree from slight spasmodic twitching of the face and vibratory motion of the eye-balls up to violent contractions of the muscles of the trunk and extremities, take place, and are usually soon followed by paralysis of one side, the opposite side continuing to be convulsed at intervals. The child lies raving and insensible; moaning and sighing, waving the unpalsied hand through the air, and rolling its head from side to side on the pillow. The cheeks are alternately flushed or pale; the eye half closed, as if from partial paralysis of the levator palpebrarum; the conjunctiva bloodshot, and the cornea dim and covered over with a slimy secretion; the pupil

is dilated, the teeth grind violently together, or there is a frequent smacking of the tongue and lips. The balance of the circulation is lost, the skin being dry and burning in some parts, and drenched with partial but profuse perspiration in others. The feet grow cold, the pulse gets weaker and weaker, the respiration unequal and stertorous, and a violent convulsion often closes the scene.

The length of the third stage is even more uncertain than that of the two preceding, varying from a few hours to one or even two weeks.

The duration of the whole disease, where the elements of which it is made up are so variable, is necessarily very uncertain. It may be stated approximatively at from two to three weeks, but it is generally nearer to the latter than the former. There has, however, been the greatest difference of opinion as to the time the disease lasts, arising partly from the variety which actually exists in different cases, and partly from the difficulty, in those cases where hydrocephalus is grafted on a previous disease, of ascertaining precisely the period at which it originated. Fothergill, Cheyne, Gölis, and the majority of writers think it usually runs its course in less than twenty-one days; whilst Whytt, on the other hand, has attributed to it a period of from four to six weeks, and Frank has mentioned a case which lasted the longest of these periods. It seems to be considerably influenced in this respect by age, as in very young infants it is often over within a week; and Coindet has mentioned one instance which terminated fatally within three days. A still more rapid species, in which effusion and death take place within a few hours from the commencement of the attack, has been described by Gölis under the name of the water-stroke (*wasserschlag*), or hyperacute hydrocephalus, which may, according to this writer, be either an idiopathic affection, or else the consequence of the repulsion of some of the exanthemata, or of the suppression of some cutaneous discharge, (as that from *crusta lactea*, *tinea*, sore ears, &c.) or of the sudden and imprudent checking of a diarrhoea, dysentery, or perspiration. The precursory symptoms in this variety are either absent or so slight as to escape notice; and the stages of inflammation and effusion seem to be almost coincident, the fluid being poured out at the very onset of the disease. Such a disorder rarely leaves any time for treatment, and it terminates almost invariably in death. On dissection, a fluid more turbid than that usually found in hydrocephalus is detected in the ventricles. Of the cases of hydrocephalus appended to Gölis's work, the most rapid was one which terminated fatally in twelve hours; in the majority death seems to have occurred about the seventeenth or eighteenth day. Springel has assumed fourteen days as the average duration. When the disease makes its attack in a very violent form, infants may be cut off by convulsions in its very commencement.

Prognosis.—Hydrocephalus has always, and with too much reason, been considered a very

fatal disorder. It does not, however, as some would have us believe, universally and necessarily terminate in death. Since its diagnosis in the earlier stages has become more accurate, and its inflammatory nature in the majority of cases been generally recognized, patients have been saved much more frequently than formerly. Recovery has been known to take place after the occurrence of all the most decided symptoms of the disease; slow pulse and stupor, strabismus, dilatation of the pupil and blindness, convulsions and paralysis. In Dr. Cheyne's essay numerous instances of recovery under the influence of judicious and energetic treatment are detailed. At Geneva, according to Odier, about eighteen children on an average are attacked by it yearly, and of these about six or one-third recovered. Of the eleven cases recorded by M. Brichteau, four recovered; of Dr. Mills' twenty-eight cases, seven; and of the thirty-seven given in Gölis's work, five had a similar termination. In the whole practice of the latter physician, which has been unusually extensive in the diseases of children, forty-one cases of recovery from hydrocephalus have been met with; these were, however, very early seen, and being subdued in the inflammatory stage, have been thrown in his tables under the head of inflammation of the brain. These results are very gratifying to those who feel an interest in the progress of medical science, and form a pleasing contrast to the desponding views of Whytt and Fothergill, and the other early writers on the disease. "So long," says Dr. Cheyne, "as the pulse continues steady and the breathing natural, we are not to be prevented by the most alarming symptoms from an employment of active remedies." A very few instances of what may almost be called spontaneous recovery, so inefficient was the treatment employed, are to be met with in medical writings, and must still farther encourage our exertions on the behalf of those labouring under the disease. Willan speaks of an infant which recovered in the fifth week of its illness, though its case had been abandoned by the medical attendants as hopeless. No medical man who has a due regard for his own character or for the feelings of the friends of a hydrocephalic patient, should desert a case of this kind at any stage, however unpromising it may be. Under circumstances apparently desperate, a temporary or even permanent amendment will sometimes most unexpectedly take place; and if a new medical attendant has been called in, what is perhaps only the effect of an effort of nature will be set down to the credit of his superior penetration and more judicious measures. After effusion has occurred, the disease is generally supposed to be utterly hopeless; but such a dogma should be allowed to exert no influence on our practice, both because it seems unwarrantably to limit the powers of nature, and because we possess no unequivocal signs from which we can certainly conclude that such effusion has actually taken place; for all the symptoms usually attributed to it may, it is now well known, be produced by inflammation alone.

In forming our prognosis, much attention must be paid to the state of the pulse and of the excretions. If the pulse, from being very quick, falls slowly and moderately, the prognosis must be more favourable than where it comes suddenly down; the former shewing a diminution of fever, whilst the latter might imply that the second stage of hydrocephalus was about to establish itself. Inattention to this point in suspicious febrile cases has often led practitioners into disagreeable mistakes; the fall of the pulse inducing them to give a very favourable prognosis, and pronounce the disease at an end at the very moment it was about to assume a new and fatal aspect. Where the pulse, on the other hand, has already become unnaturally slow, a slight increase of frequency may be considered a favourable circumstance; whilst a rapid and very considerable rise would point to the commencement of the final stage.

An increased facility in procuring stools, an improvement in their appearance, a plentiful secretion of urine, a profuse warm perspiration, or a running from the nose, are to be considered promising circumstances. It is on the latter of these evacuations that the vulgar reckon most, and empirics often take advantage of their credulity to exhibit powerful emetics, a practice which is said, we know not how truly, in some rare instances to have been successful. We must beware, however, of attributing too much importance to any single symptom: thus we have known a profuse perspiration about the head and neck occur though the disease was rapidly hastening to a fatal conclusion. Indeed partial perspirations here, as in most other cases, are generally to be looked on with a suspicious eye: in the stage of palsy they are the usual forerunners of death.

If under the influence of powerful medicines or otherwise, an intermission of symptoms for two or three entire days takes place, we may entertain good hopes of recovery; but unfortunately this cessation is rarely so prolonged. In the great majority of cases the truce is a brief and fallacious one, the irregularity of pulse, headach, vomiting, &c. recurring in a few hours, and the disease proceeding rapidly to its fatal termination. Even in cases of apparent recovery we must not be too sanguine as long as the pupil continues dilated, or contracts but sluggishly on exposure of the eye to a strong light.

Where the acute disease supervenes on the chronic, the prognosis is very unfavourable; not indeed on account of any irritating or corroding quality which the effused fluid has, as some of the German writers fancy, contracted, but on account of the almost irremediable nature of the exciting cause and the debilitated state of the constitution generally. Where it occurs during the slow and imperfect convalescence from an acute disease, or develops itself in the course of hooping-cough, infantile remittent, or painful dentition, or succeeds to some scrofulous affection or other tedious disease by which the powers of the constitution have been greatly reduced, recovery very rarely takes place. This

is attributable in some of these instances, partly to the extreme difficulty of detecting the disease of the head in its incipient stage, and partly to the debilitated state of the patient not admitting of the employment of those active measures which the nature of the local disease requires. That variety which occasionally occurs as a sequela to scarlet fever is generally more within the influence of medicine than the other kinds alluded to above. On the other hand, that which occurs in the early stage of this disease or of the measles, usually assumes a very violent form, and is, as we have already stated, almost always rapidly fatal.

Amongst the possible terminations of acute hydrocephalus is its passage into the chronic form; but this is extremely rare, and is scarcely to be desired, being very liable to be accompanied with blindness or deafness, idiocy, epilepsy or paralysis, or some other lamentable impairment of the functions of the nervous system, arising from the serious injury which the brain has undergone. Such consequences are, however, not universal. Guersent mentions a case which, having become chronic, got completely well on the spontaneous occurrence of a cutaneous eruption, and that too after all the ordinary means of treatment had proved ineffectual.

It has appeared to Dr. Cheyne that hydrocephalus is more frequently cured when it occurs in such constitutions as have a decided predisposition to it, which may always be presumed when several individuals of the same family have been successively attacked. This apparent paradox is perhaps only explicable on the supposition that previous losses dispose and enable parents more early to detect the incipient symptoms of the disease, and thus lead to the employment of an appropriate treatment at that period when medicine is most likely to be of any avail. Success has by some been thought most probable in those cases which come on slowly and gradually, and thus afford ample time for treatment. According to Abercrombie and Gölis, on the contrary, those are the most favourable in which the symptoms indicate very active inflammation, and admit of energetic treatment; whilst the least promising cases are those where the inflammation is of the low or scrofulous kind. "In all," says the first of these writers, "the period for active practice is short, the irreparable mischief being probably done at an early period of the disease."

Diagnosis.—There is perhaps nothing more characteristic of this affection of the brain than the rapid fluctuations which the several functions of the body undergo, and that often within a very brief space of time. This mutable condition is indicated in the cerebral functions by the state of the intellect and senses, now unnaturally acute, again dull, and at times altogether obliterated. The muscular system is at one moment unaffected save by debility, and the next moment perhaps convulsed or paralysed. The pulse and capillary circulation are constantly varying under the influence of slight or inappreciable causes, the face being

at one moment flushed and at the next deadly pale, whilst heats and chills, perspiration and dryness of the surface, rapidly alternate. The respiration likewise undergoes endless changes in force and frequency. The functions of the digestive organs are equally variable, anorexia and incessant vomiting being succeeded by an apparent insensibility of stomach, or a ravenous and indiscriminating appetite.

Of effusion having actually taken place, there is, as we have already stated, no symptom nor even set of symptoms, which can afford us *certain* evidence. Somnolence, strabismus, convulsions, and partial paralysis, which were once so much confided in, have lost much of their credit since pathological anatomy has been more diligently cultivated; and numerous cases are now on record where they all existed though no water was found on dissection. Coma, immobility and dilatation of the pupil, and blindness, and sundry other symptoms which have been supposed by later authorities to be more worthy of reliance, will also frequently deceive us as far as effusion is concerned: their true value consists in fixing attention on the state of the brain itself. When we recollect that the effusion is a mere result or consequence of the disease, and reflect on the complicated state of cerebral derangement which often precedes or coexists with it, the difficulty of recognizing it with certainty during life will cease to surprise us. In a practical point of view, moreover, it is of less importance than is generally imagined. It is not the effusion, so much as the morbid state of the parts within the cranium which leads to it, which is the legitimate object of treatment: over the former, when it already exists, many doubt whether medicine can exert any influence.

The difficulty of distinguishing hydrocephalus in its earlier stages from many of the febrile affections to which children are liable is often very considerable. We may generally avoid confounding it with the infantile remittent fever by attending to the extreme irritability of stomach, and its aggravation by the erect posture and by motion—the greater severity and constancy of the headach—the disposition to somnolency, the child often falling asleep the moment after it has been replaced in bed, or after it has been answering our questions—the knitting of the brows and aversion to light and noise, the pupil being at first contracted and subsequently unnaturally dilated—the caution in moving the head, and the frequent raising of the hands to it—the thrusting back of the neck—the variability and extreme excitability of the pulse—the green stools or obstinate costiveness. The morning remissions moreover, if they occur at all, are much less marked in hydrocephalus than in the infantile remittent. Amidst our efforts to establish a diagnosis in any particular case, we must not forget that diseases are at times, in the language of the older writers, convertible into each other; or that, to use the more moderate phrase, complications may arise in their course, and the secondary affection eventually predominate over the original. It

is thus that in the course of infantile fevers hydrocephalus frequently comes on, and often with such insidious advances as altogether to elude observation almost up to the very moment of its fatal termination; we confess we have even remained doubtful as to the existence of the disease within the head till the scalpel revealed its presence. Where infantile remittent is about to pass into hydrocephalus, the remissions become gradually less and less distinct. Pain is in some cases never complained of.

Fevers of a typhoid type are comparatively rare in children, and when they do occur can scarcely, with ordinary attention to the symptoms, be confounded with hydrocephalus. Gölis has, with a truly German patience, been at the pains of drawing a long parallel between the two diseases. The more equable pulse, the diarrhoea with dark and fetid stools, the trembling tongue, petechiæ, and low muttering delirium, the tumid belly, supine posture, and sliding to the bottom of the bed, to say nothing of the absence of all the more striking symptoms of hydrocephalus, will scarcely suffer us to confound a case of typhus with even the obscurer examples of the former disease.

In connection with low and protracted fever, symptoms frequently occur, as has been remarked by Abercrombie, which seem to indicate serious affection of the brain, and yet these shall all disappear as the fever subsides. Thus he gives a case of a child labouring under a tedious disorder of this kind, accompanied with stupor, blindness, dilated pupil, and squinting. After lying speechless for near a month, it gradually recovered after a copious discharge of matter from one of the ears. We think it probable, however, that the essential part of hydrocephalus, namely inflammation in the central parts or at the base of the brain, was present here, and that the fever was throughout only symptomatic, and its cessation attributable to the escape of pus from the external meatus.

A want of correspondence in the symptoms has been pointed out as one of the marks of this disease of the brain. Thus, when the headach is greater or more permanent than accords with the degree of fever, and especially if the pain increases in intensity as the pulse falls, our suspicions should be awakened. Brichteau dwells on the slightness of the thirst and its total disproportion to the fever. This, however, is by no means invariably the case. Many children labouring under hydrocephalus drink largely, so that M. Brachet, another French writer, has even considered the extreme avidity with which they seize the vessel containing their drink as one of the most remarkable symptoms of the disease.

The frequent and deep sighing and the peculiar scream, such as might be uttered under the agonies of a severe surgical operation, are also very characteristic of the disease.

Severe pains appearing successively in different parts of the body, and for which we cannot in any way account, should in children as well as in adults always excite suspicion, and make us turn our attention to the nervous sys-

tem, and especially to the state of the organs contained within the cranium and spine.

The diagnosis is peculiarly difficult in feeble children who have been exhausted by long previous illnesses, as scrofula, painful dentition, or chronic disorders of the digestive organs already attended with vomiting. Quin met with a case of acute hydrocephalus which proved fatal in seven days, in which there was no evident division into stages, no dislike of light, nothing characteristic in the pulse, no dilatation of the pupils, nor any violence of headach; and Rush alludes to similar cases.

In very young infants the detection of the disease in its early stage requires the closest observation. Long-continued wakefulness, or starting from sleep with a cry of alarm, or prolonged screaming without any obvious cause, should always awaken our apprehensions; and when the infant subsequently lies moaning and drowsy, and rolling the head from side to side on the nurse's arm, or thrusting it back against the pillow; when there is frowning and aversion to light, a contracted state of the pupil, and unusually frequent vomiting, our suspicions are almost converted into certainty. The negative indications also, or the absence of well-marked disease in the chest or abdomen, will frequently throw additional light on the nature of the case. The face, as has been remarked by Cheyne, is expressive rather of uneasiness than of acute pain; nor is there the extreme violence of temper or the alternate throwing out and drawing up of the legs which accompanies colic and griping pains in the bowels. "In no other infantine complaint do we observe the same knitting of the eye-brows unaccompanied with crying. The head hanging over the nurse's shoulder, and the half-closed eye-lids are also alarming symptoms." Where convulsions together with strabismus, dilated pupil, blindness, and a comatose state, have already taken place, the nature of the case is but too evident. Convulsions, as we have already stated, sometimes occur even at the commencement of the disease; no one, we believe, at the present day considers them ever to be a purely idiopathic affection; whatever may be their exciting cause, they indicate serious functional derangement of the nervous system, and what was originally perhaps only sympathetic disorder, may, if neglected, terminate in organic disease. When convulsions or spasm of the glottis, which may be considered as a modification or local species of them, resist the ordinary means for correcting disordered states of the digestive organs and improving the general health, we should suspect a tendency to disease of the brain, and take our measures accordingly.

A readiness in detecting that species of hydrocephalus which occurs some days or weeks after an attack of scarlatina, is peculiarly desirable, both because it is an affection by no means of rare occurrence, and because, if taken early, it is the most manageable perhaps of all the forms of dropsical effusion within the head. The first symptom which warns us

of its existence is severe headach; and if this be neglected, convulsion, loss of sight, and a comatose state soon follow. Like the general anasarca which usually accompanies it, it is a truly inflammatory affection, and may be often speedily arrested by the use of active antiphlogistic measures. It is most to be dreaded when it makes its advances in a slow and insidious manner. The sudden disappearance of the anasarca, when unaccompanied by any increase in the evacuations, occasionally gives rise to this affection of the head.

A lethargic state, with irregularity of the pulse and dilatation of the pupil, occurring with or without fever, occasionally depends on constipated bowels, and vanishes rapidly on the exhibition of an active purgative; but it is highly probable that such cases, if neglected, would often pass into confirmed hydrocephalus; for we cannot agree in opinion with Willan and Underwood in thinking that cases, though they possess all the characteristic symptoms of hydrocephalus, yet are not really allied to that disease provided they yield to the free use of purgative medicines. Dilatation of the pupils has sometimes seemed to depend on the presence of worms in the intestines.

In all cases of doubt it is safer to lean to the supposition of the disease being hydrocephalus, and to treat it as such. From this, even though we should be in error, little inconvenience can arise; whilst on the other hand, if we wait until unequivocal symptoms of the disease in its confirmed state have developed themselves, all our efforts at checking its further and fatal progress will too often be of no avail.

Dr. Gooch has described a peculiar state of the brain occurring in infants which has usually, but erroneously, been attributed to congestion of this organ; whereas it seems really to depend on the very opposite state, or a deficiency of blood in it. It is in children of from two months to two or three years old that it usually makes its appearance, and generally in such as are small and delicate, and have been exposed to some previous debilitating cause. The leading symptoms consist in heaviness of the head, drowsiness, and languor. There is an absence of heat and of all the symptoms of fever, the skin being occasionally even colder than natural. The tongue is slightly white, and a transient flush at times passes over the cheek. There are no signs of pain. Under the antiphlogistic treatment usually pursued in acute hydrocephalus, consisting of leeches, cold applications, purgatives, and especially calomel, all the symptoms become aggravated, the child growing colder and more languid, the pulse quicker and weaker, and death by exhaustion takes place after a few days; whilst, on the contrary, several have recovered under the use of an abundant supply of light nourishment, and the cautious employment of ammonia and other stimulants. In two cases only did he observe symptoms of oppressed brain, coma, stertor, dilated and motionless pupils; and this was only for the last few hours before the fatal termination.

On dissection, the brain is found pale and bloodless, with no other morbid appearance than perhaps an increased quantity of serum in the ventricles. The late Dr. Armstrong has applied to an affection in many respects very like that just described, the name of "hydrocephalus from venous congestion;" whilst by Dr. Darwall it has been called asthenic hydrocephalus.

The disease, however, to which the term hydrocephalus is, by the majority of writers of the present day, conventionally restricted, is so different from this passive effusion, as well in most of its symptoms as in the treatment which it requires, and in the morbid condition of the brain discovered after death, that no benefit, we think, can arise from comprising both under the same name. The term, in regard to its derivation, is, we admit, equally applicable to each; but this only shows the impropriety of having named them, not from any thing essential, but from an effusion which may be present or absent in both, and is consequently characteristic of neither.

The above described morbid condition in infants has also been noticed by Dr. Marshall Hall, who was generally able to trace it to the diarrhoea of weaning, or to leeching for some previous complaint, or some other cause of exhaustion. He too, like Gooch, believes that it is often mistaken for "hydrancephalus, or inflammation of the brain." There is at first, according to his observation, great restlessness with irritability of temper, pale and anxious countenance, and frequent pulse; dozing and deceptive appearances of amendment succeed; but the pulse continues to rise, the cheeks and the extremities grow cold, the voice and cough husky, and the patient soon sinks exhausted;—a termination which may, however, be often averted by a proper supply of nourishment and a cordial soothing plan of treatment. Dr. Abercrombie, in like manner, in the last stage of diseases of exhaustion has seen both adults and children, but especially the latter, fall into a state resembling coma for a considerable time before death; the pulse still continuing to be distinctly felt, though feeble; the face pale, the pupils dilated, and the eyes open, but insensible. He has known children, after lying for a day or two in this kind of stupor, recover under the use of wine and nourishment. This state, which seems to correspond very nearly to the apoplexia ab inanitione of the older writers, is supposed by Dr. Gooch to consist in impairment of the nervous energy, or deficient cerebral circulation. Profuse hemorrhage is well known to be capable of producing dilatation of the pupil and blindness; and when animals are bled to death, convulsions very usually occur, and more or less serous effusion takes place in the brain, as appears from the experiments of Dr. Leeds.

Appearances on dissection.—There is sometimes, in consequence of previous inflammation and adhesion, considerable difficulty in separating the skull-cap from the dura mater, and the former is occasionally thinner, more trans-

parent, and of a bluer colour than usual. When we come to examine the state of the parts within the cranium after death, we usually find the vessels on the surface of the brain in a state of considerable congestion. A network of florid vessels is occasionally observed in the pia mater, and even patches of extravasated blood, indicative of high inflammatory action, are occasionally detected. This membrane at times also adheres more strongly than natural to the brain. An effusion of serum underneath the arachnoid, and filling the space between the convolutions, is very frequently observed. When it is considerable in quantity and of a yellowish hue, it might be mistaken by a superficial observer for a gelatinous effusion. In some instances it has a sero-sanguinolent character. Opacity and thickening of the arachnoid membrane, and depositions of coagulable lymph, or more rarely of puriform matter on its surface, or between it and the pia mater, are amongst the more commonly observed morbid appearances, and prove unequivocally the inflammatory nature of the affection. These occur especially at the base of the brain, about the pons varolii and decussation of the optic nerves. That these and many other characteristic morbid appearances should have escaped observation in the slovenly manner in which the brain used too often to be examined by slicing it from above downwards in situ, is not wonderful. Before commencing the dissection of the brain itself, it ought to be removed altogether from the skull and inverted into a plate, so as to enable us accurately to examine the important parts at its base.

Adhesions between the opposite surfaces of the arachnoid through the medium of false membrane, are sometimes, though rarely, observed. The arachnoid is occasionally covered, especially when it lines the ventricles, with minute granulations, which give it a rough appearance. They are probably one of the many forms which the effused coagulable lymph assumes, and require a good light for their detection. We must not confound with these granulations the bubbles of air which at times exist beneath the pia mater, and which may be distinguished by their vanishing on raising this membrane.

The mass of the brain itself, in some rare instances, has appeared evidently infiltrated with serosity. Gólis mentions such a case, in which the fluid could be expressed from the cerebral substance as if from a sponge; and Cheyne also has noticed this appearance of increased moisture on making sections of the organ.

A frequent appearance is that of an unusual number of bloody points in the cut surface of the brain, indicating a considerable increase in its vascularity.

The substance of the brain in acute hydrocephalus is generally softer than natural; and this is especially observable towards the central parts. Yet in some cases, and especially in those which run a very rapid course, it is found to have retained its usual firmness.

In most instances the ventricles contain a considerable quantity of fluid, which is usually more limpid than that found in the other serous cavities. Sometimes, however, it presents a turbid, whey-like, or puriform appearance, with shreds of coagulable lymph floating in it, as well as lining the walls of the ventricles; and this is particularly the case in the most acute and rapid examples of the disease. The existence of a fluid may often be predicted before we have punctured the ventricles, from the feeling of fluctuation communicated to the finger applied to the surface of the hemispheres, as well as from the flattening of the convolutions. The quantity of water varies from a few tea-spoonfuls to seven or eight ounces: four or five ounces may be stated as the average. Of this the greater part is contained in the lateral ventricles, the posterior horns being usually much enlarged, and the anterior portion of the fornix elevated so as to make the opening of communication very free with the third ventricle, in which, as well as in the fourth, and in some very rare instances also between the layers of the septum lucidum, the effused fluid is likewise found. The choroid plexus is very generally remarkably pale. Small vesicles, not unlike hydatids, are occasionally found attached to the pia mater; and we have seen such adhering to the choroid plexus. They seem to owe their origin merely to a circumscribed sub-arachnoid infiltration; the serous membrane being detached by the effusion at a given point, and distended into a small cyst.

The septum lucidum, the fornix, and other parts forming the walls of the ventricles, are often found in a state of softening, being of a pulpy or occasionally even of a creamy consistence, whilst the lining membrane of these cavities displays equal evidence of inflammation by its opacity, as well as by the layers of coagulable lymph with which it is at times overspread. A lacerated opening in the septum lucidum occasionally exists, and forms a new and unnatural communication between the lateral ventricles. We have seen the infundibulum and the cellular membrane in the structure of the pituitary gland distended with serous effusion into the form of a little bladder. This, by its direct pressure on the optic nerves, in addition to that to which they are exposed from the lymph effused at the base of the brain, and from the dilatation of the ventricles, must tend to complete the derangement of the functions of vision.

Laennec has spoken of minute tubercular granulations dispersed through the brain, and discoverable by a careful microscopic examination; but as their existence has not been confirmed by subsequent observers, it is probable they are at most only a casual occurrence.

Other morbid appearances, of a date anterior to the hydrocephalus, and occasionally, no doubt, its cause, such as tubercles or abscesses in the brain, caries of the petrous portion of the temporal bone, &c. not unfrequently co-exist, and should be carefully sought for.

With regard to the nature of the effused fluid, it differs somewhat from that found in the other serous cavities, being for the most part not coagulable by heat or acids; this is, however, by no means universally the case, a slight coagulation having in some instances been detected by Dr. Baillie, Dr. Blackall, and others. It has been carefully analysed by Marcet. Of 1000 parts operated on, 990·80 were water; 1·12 muco-extractive matter, with a trace of albumen; 6·64 muriate of soda; 1·24 sub-carbonate of soda, with a vestige of an alkaline sulphate; ·20 phosphate of lime, with traces of phosphate of magnesia and of iron. Acids or heat, according to this chemist, did not produce any decided coagulation.

It has been already stated that abdominal affections often complicate hydrocephalus, that they frequently precede it, and are probably not very rarely its exciting cause. On dissection, unequivocal examples of disease in the viscera of the abdomen have been detected in too many cases to be considered a mere casual coincidence. Thus the liver has been found enlarged, and presenting evident traces of inflammation on its surface, and adhering through the medium of organised lymph to the neighbouring parts. Tubercles on its surface or in its substance, as well as in that of the spleen and mesenteric glands, are occasionally observed. We have found the mucous membrane of the stomach and intestines inflamed, and the patches of Peyer's gland much developed, and such firm contraction of the intestinal tube as to give it in parts the appearance of a solid chord. This spasmodic state, when existing in the large intestines, enables us to account for the great difficulty which sometimes attends the administration of enemata during the latter part of the disease. We have likewise met with intus-susception of the small intestines, an appearance which has been alluded to by several writers on the disease. The spasmodic state of the intestines which is thus evinced is probably in some degree analogous to the convulsive actions in the voluntary muscles, and takes place like them under the influence of the morbid state of the brain; at least, they do not seem to be attributable solely to the irritation in the mucous membrane, both because such extreme contraction is not usually observed in instances of uncomplicated inflammation of this membrane, and because we have found it greatest in those parts of the intestines which presented least appearance of inflammation. We have noticed a similar constriction of this canal after death by tetanus, where there existed no inflammation of the intestines.

The peculiar green colour of the stools in hydrocephalus has been attributed to their union with morbid bile. We were first led to entertain doubts of this opinion being universally correct, and to ascribe the appearance in question rather to a morbid secretion from the glands of the intestines themselves, by observing that the peculiar porraceous tinge was not acquired in perfection till the feces had reached the lower part of the small intestines, the

contents of the upper portion being of a pale drab colour, whilst the bile in the gall-bladder was of a yellow colour, and without any tinge of green.

The assertions of Dr. Cheyne as to the frequency of disease in the liver and intestines have been corroborated by the subsequent observations of Dr. A. T. Thomson, Mr. Cooke, and others. In eleven dissections of patients dead of this disease, Dr. Thomson found traces of inflammation of the liver in nine, inflammation of the colon in the tenth, and intus-susception of the jejunum in the remaining one; whilst in three out of Mr. Cooke's four cases the liver was found diseased. Dr. Wilson Philip's experience leads him to the conclusion that five out of six cases of hydrocephalus arise out of the derangement of the digestive organs; and Abernethy has mentioned three cases of hydrocephalus in all of which the liver and bowels were notably diseased.

Though evident traces of inflammation in the brain or its membranes are detected in a very large proportion of cases, yet there are a few in which a trifling effusion of serum in the ventricles or under the arachnoid is the only morbid appearance discoverable; there being neither congestion of the vessels nor effusion of coagulable lymph, nor softening of the central parts of the brain, the whole organ being as firm and perhaps even paler than in its natural state. Such is, as we have already stated, usually found to be the case in infants who have died with the symptoms of passive effusion previously described. M. Brichteau, in the *Archives Générales* for the year 1824, has described a case where most of the usual symptoms of hydrocephalus had existed; and yet, on dissection, a limpid serous fluid in the ventricles was almost the only thing detected, and was not by him thought to be the result of inflammatory action: by many, however, we believe it would have been considered as an instance of low inflammation in the arachnoid. Of late years, since pathological investigations have been conducted in a more careful and methodical manner, it has been much more rare to hear of cases which, having possessed the whole assemblage of symptoms characteristic of acute hydrocephalus, yet present on dissection no indubitable marks of inflammatory action. Guersent candidly confesses that amongst his earlier dissections he has notes of many such cases in which no allusion to inflammatory appearances is made; but that, as he became more accurate in his mode of examining the brain, the instances in which proofs of their existence could not be detected became infinitely rarer.

Theories of the disease.—The uncertainty which has prevailed as to the true nature of acute hydrocephalus has given rise to a corresponding diversity of opinion as to the appropriate place for it in systems of nosology. It was long confounded with apoplexy, till Whytt, by a closer investigation of its symptoms, became convinced that it was much more nearly allied to chronic hydrocephalus. Cullen, who at first classed it along with

chronic hydrocephalus, in a later edition of his nosology made it a species of apoplexy, under the name of apoplexia hydrocephalica. By Macbride it was placed along with fevers, under the name of febris nervosa hydrocephalica; and a similar view of it was taken by Pinel in the earlier editions of his *Nosographie Philosophique*, in which it bears the name of cerebral fever; but he subsequently restored it to its old place amongst the dropsies: there is however, usually no evidence of any dropsical diathesis, effusion into the other cavities, or swelling of the face or limbs, scarcely ever co-existing with it. The investigation of the disease by Quin and Rush, proceeding on the basis of pathological anatomy, the only solid groundwork of nosological arrangement, led to a more correct conception of its nature, and demonstrated its affinity in the great majority of instances to the phlegmasiæ. Subsequent inquiries, both in this country and on the continent, have tended to confirm the justice of this manner of considering the subject, and have proved that the effusion is almost always a secondary phenomenon occurring in connection with obvious morbid changes in the brain or its membranes, and in a very large proportion of cases demonstrably the results of inflammation. So fully convinced is Rostan of the effusion being always consecutive to cerebral or meningeal lesions, and never constituting an essentially distinct disease, that he proposes that the term hydrocephalus should be altogether expunged from our tables of nosology. As the effusion and other morbid appearances are such as to indicate inflammation of the serous membrane, the disease has been treated of by several foreign writers under the head of arachnitis of the ventricles and base of the brain; whilst others, conceiving that inflammation of the cerebral structure itself often precedes that of the membranes, have referred its symptoms to the head of cephalitis. Thus, by Conradi it is called "encephalitis exsudatoria infantilis," and by Coindet, "cephalite interne hydrencéphalique."

That the effusion does not constitute the most important feature in the disease, and that it is not indispensable to the production of any of the symptoms which characterise hydrocephalus, we have a double proof; first, in the occasional absence of these symptoms where effusion to a considerable extent is detected on dissection; and secondly, in their being sometimes present, and that in a very marked degree, when an examination of the brain after death has shown that no effusion had yet taken place. There is sometimes even reason to think that the inflammatory tension is temporarily relieved by this increased action of the exhalant vessels: this can, however, be the case in those instances only where the effusion is moderate. Where it takes place rapidly, and to a considerable excess, it cannot fail to add still further to the derangement of the cerebral functions, and to manifest its presence by symptoms indicative of compression under some circumstances, and of irritation under others. We cannot, therefore, concur

in opinion with a late writer, who supposes that the increasing fluid, by stimulating the brain, may occasionally answer a beneficial purpose, and give rise to that momentary recovery of the senses and of the intellect which so often takes place before the fatal termination. Such fleeting and fallacious indications of improvement in the state of the cerebral functions should perhaps rather be attributed to a temporary diminution in the quantity of water in the ventricles under a casually increased action of the absorbing vessels. This partial re-absorption of the aqueous effusion some time previous to death is rendered probable by the instances of a similar diminution of effused fluid in the extremities and other parts of the body lying open to our observations being by no means rare in dropsical subjects at this period. It is only to some change in the state of the effused fluids, or of the circulation within the brain, that we can look for an explanation of this fact; for as to the alterations of structure and consistency which have occurred in any portion of the cerebral mass or its membranes, it is inconceivable that they should undergo any sufficiently rapid modification to account for it. As to the presence of absorbing vessels in the brain, so long a subject of dispute, the changes which are now so well known to take place in the apoplectic coagulum cannot leave a doubt. The occasional diminution of the effused fluid in chronic hydrocephalus under the influence of pressure or other methods of treatment, is also conclusive on the same point. Indeed the analogies in favour of the existence of such vessels within the brain are so strong, that it seems wonderful that there ever should have been any scepticism on the subject. It is altogether inconceivable that the fluid, which even in a state of health always lubricates the serous cavities within the cranium, should, unlike that in the thorax or abdomen, be stagnant and incapable of removal. Cheyne suggests that the effused fluid may answer the useful purpose of supplying the place of the cerebral matter removed by absorption, thus giving support to the brain, and enabling it in some degree to continue its functions; and hence he conceives that any sudden withdrawal of the water, so far from being desirable, might even have a fatal effect.

Morgagni was one of the first pathological anatomists who pointed out the very frequent dependence of effusion on organic disease of the brain; and Portal has likewise long since insisted on the very secondary importance of the latter in determining the indications of cure. The belief in the inflammatory nature of hydrocephalus, since it was first promulgated by Quin and Rush, has been slowly but steadily making its way both in this and all other countries where medical theories are in any degree under the influence of morbid anatomy. Dr. Garnett argued in favour of this view of the disease from the buffy state of the blood, the acuteness of the pain, the character of the pulse, the benefit received from antiphlogistic measures early employed, as well as from the aggravation en-

suing upon the use of stimulants, and finally from the appearances found on dissection. Similar views were followed up with great industry and ability by Dr. Cheyne, who showed that the opinion of Fothergill, who attributed the effusion to the rupture of a lymphatic vessel in the brain, as well as that of Whytt, who ascribed it to a watery state of the blood, or to a laxity of the exhalents, and that of Darwin, who thought it consisted in a debility of the absorbent vessels, were all hypothetical and untenable; whilst he proved by numerous carefully made dissections that dropsical effusion here, as in so many other cases, is, to use the language of Heberden, not so much a disease in itself as a symptom of one. The opinion of Cheyne seems to be, that hydrocephalus owes its origin in the first instance to inflammation; that this gives rise to a morbid accumulation of blood in the head or venous congestion; and that effusion is the ultimate result. Occasionally the concatenation of morbid actions can be traced still farther back: thus there is often, first, disease of a distant part, then increased irritability, which is soon attended by increased arterial action, absorption of the substance of the brain, venous congestion, and finally effusion. "There is no proof whatever," says the above-named writer, "that the effusion into the ventricles is the cause of any of the violent symptoms."

The greater or less quantity of fluid found in the ventricles in acute hydrocephalus seems to depend on the length of time which the patient has continued to live after the commencement of the second stage. Though the state of the disease may undergo some modification by the occurrence of effusion, yet there is much reason to believe that some degree of inflammation exists to the very end. Cheyne, although a strong advocate for the inflammatory nature of hydrocephalus, by no means goes the length of Dr. Rush, so as to believe it merely a modification of phrenitis. He points out, on the contrary, with his usual accuracy, many striking marks of distinction between the two diseases, deduced from their causes and symptoms, from the ages respectively prone to each, as well as from the morbid appearances found after death. "Hydrocephalus," he concludes, "appears to consist in a diseased action of a peculiar kind, but of what kind we can as little explain as we can the nature of the serofulous or syphilitic action."

According to Abercrombie, hydrocephalus is originally an inflammatory affection; in its most ordinary form seated chiefly in the substance of the central portions of the brain, and terminating generally in ramollissement of those parts, combined with serous effusion into the ventricles. It may, however, prove fatal, and have all the symptoms commonly considered as those of hydrocephalus, without any effusion. Thus we occasionally observe coma of long continuance, though on dissection no such cause of it is detected; and on the other hand, effusion has been unexpectedly found though coma had never manifested itself. Again, even when this symptom does exist, it

may sometimes be entirely removed by purgatives and other antiphlogistic measures, and yet the disease proceed uninterruptedly to its fatal termination. In the cases which have been published by the same able physician, we meet with every variety in the state of the pulse, the vision, and the intellectual functions; so that we can obtain from none of these sources indubitable evidence of effusion having taken place. Though inflammation of the central parts of the brain constitutes the most frequent modification of hydrocephalus, he admits that it may take place in connexion with inflammation of other parts of this organ, or of the membranes which envelop it. He has noted but two instances in which he did not succeed in demonstrating other inflammatory appearances besides the effusion of serum; and in these the disease presented itself in the most insidious and chronic form, and offered a remarkable contrast to the active symptoms of what he considers the usual species of the disease. As to the serum, he believes, that even though it were absorbed, the patient's condition would be little improved, as the softening or disorganization of the brain would remain behind. In a word, the coma and other symptoms of hydrocephalus are the effect, not of the effusion, but of that morbid condition of the brain of which it is itself the consequence.

Lallemand conceives that the inflammation in hydrocephalus may commence either in the cerebral substance, and subsequently extend to the membranes of the brain, and thus induce effusion; or, on the other hand, begin in the arachnoid, and extend, after a longer or shorter period, to the brain; but of these two origins he considers the latter by much the most frequent. In their earlier stages he believes that they may often be distinguished from each other. The possibility of their commencing simultaneously in some cases, in both these parts, under the influence of a common cause, must not, however, be forgotten. Inflammation of the membranes, according to Lallemand, is characterised by restlessness, insensibility, convulsive affections and delirium; whilst that of the cerebral substance itself may be recognised by the gradually extending paralysis, the rigidity and pains in the limbs, together with the impairment of the memory and intellect. Inflammation of the brain itself has a rapid progress, and is speedily mortal. Hence, when the symptoms of hydrocephalus depend on inflammation of the cerebral substance, they are more severe, and the disease runs a shorter course. In several cases such inflammation has existed in the septum lucidum, fornix, and other central parts of the brain, without extending to the arachnoid where it lines the ventricles, and consequently without effusion, and yet all the symptoms of hydrocephalus have been present. Hence, he argues, it is highly probable that even in those other cases where effusion does exist, it has much less concern than the state of the neighbouring parts in producing the characteristic symptoms of the disease. From erroneous views on this subject too little attention has, he thinks, been paid in

the treatment to the ramollissement, and the efforts of practitioners have been too exclusively directed to promoting the absorption of the effused fluid.

The investigations of MM. Martinet and Parent-Duchâtelet have shewn that inflammation of the arachnoid at the base of the brain is much more common in infancy than in adults. In the latter, inflammation of this membrane occurs more frequently in that portion of it which covers the upper and lateral parts of the hemispheres, and is characterized at first by delirium, to which a soporose state, and at length coma, succeed; whereas in the arachnitis of infants there is a greater tendency to convulsive affections and less to delirium.

The inflammatory nature of the great majority of cases of hydrocephalus has also been recognized in its fullest extent by Gölis, Conradi, and almost all of the German pathologists of the present day. Formey, however, a very respectable authority, thinks that the frequency of effusion into the ventricles during childhood depends not on inflammation, but merely on a state of increased activity in the vessels of the brain, which accompanies its rapid and premature development; but Raimann with much reason believes that in addition to this state, the existence of true inflammation, either of an acute or chronic kind, is indispensable.

Causes.—Of the predisposing causes, the period of life seems to be one of the most influential; hydrocephalus being very much more frequent during infancy and childhood than at any subsequent period. The rapid evolution which the brain is then undergoing, and the great proportion of blood sent to the head, appear to be the causes of the peculiar tendency to cerebral inflammation which characterizes this age. The more early and rapid the development of the cerebral organs, the greater is the risk of hydrocephalus. Its connexion with precocity of intellect is indeed matter of daily observation, and large-headed children are generally found to be the most subject to the disease. The latter fact, indeed, is doubted by Underwood, but both Gardien and Guersent confirm the popular opinion. The greatest number of cases appear from the tables of Percival and of Brichteau to occur between the second and fifth year; but at the same time it is not infrequent in infants at the breast, or, indeed, in children of any age up to the twelfth or fourteenth year: after this period it is less common. A scrofulous habit predisposes strongly to the disease. The greatest number of cases occur in constitutions evidently of this kind. When a strumous tendency exists, all the children of a family have been known to be thus swept off in succession as they approached a certain age. Hydrocephalus and scrofulous affections seem to be mutually convertible into each other, the disappearance of scrofulous disease of the glands or joints being frequently followed by the development of hydrocephalus; while, on the other hand, all the symptoms of confirmed phthisis have been known to vanish on the occurrence of the latter affection. The disease has usually been thought to take place

most frequently in children with a fair skin and hair, pink complexion, and blue eyes. Cheyne, however, says that he has seen it oftener in those with dark eyes and dark complexion. As scrofula occurs pretty equally in both these temperaments, it is probable that hydrocephalus also is nearly as frequent in the one as in the other.

Disorders of the digestive or respiratory organs, difficult dentition, scarlatina, measles, and other diseases which induce debility or excite febrile action in the system, may, according to the intensity of their action, be placed either amongst the predisposing or the exciting causes. The frequent and indiscriminate use of calomel in children's complaints has been accused by Blackall of predisposing to the disease. This, however, can apply only to the abuse of this remedy: judiciously employed it is of the greatest utility in cutting short such indisposition as might, if neglected, terminate in hydrocephalus. The pernicious habit practised by some unprincipled nurses, of giving narcotics to infants in order to quiet them and render them less troublesome—a practice which cannot fail to derange the functions both of the digestive organs and of the brain,—has been noticed as an occasional cause of this affection. Belladonna, which is much and advantageously employed in Germany as a remedy in whooping-cough, and also as a preventive of scarlet fever, has sometimes, in imprudent hands, led to inflammation and effusion within the cranium. We have seen hydrocephalus apparently induced by the abominable custom, unfortunately not very uncommon amongst the lower classes, of giving spirits to children.

Great terror and anxiety in the mother during the last months of pregnancy has been placed by Gölis in the list of predisposing causes, in support of which he adduces the fact, that a great proportion of the children born soon after the bombardment of Vienna by the French in 1809, were seized with convulsions within a month after their birth, and died of inflammation within the cranium; effusion of coagulable lymph on the membranes, and of serum in the ventricles, being discovered on dissection. The same writer conceives that the frequent exhibition of emetics in catarrhal or other affections may occasionally lead to the disease in scrofulous children. We are not aware, however, that any facts in confirmation of these opinions have been observed in this country.

To the list of exciting causes enumerated above, we may add external injuries, such as falls or blows on the head, the extension of inflammation from the external ear to the brain. The sudden suppression of accustomed discharges, or drying-up of sores behind the ears or eruptions about the head, without an appropriate modification of the diet, or the simultaneous employment of suitable evacuations, are also amongst its occasional causes. However erroneous may have been the explanation of the facts afforded by the humoral pathology, their reality and importance are indubitable, and will be least questioned by those who have attended the most closely to the powerful in-

fluence of counter-irritation in controlling morbid determinations of blood to internal organs, and in subduing their tendency to inflammation.

Treatment.—The chances of success in the treatment of hydrocephalus depend in a great measure on the period at which it is detected. It is during the precursory symptoms, or the commencement of the inflammatory stage alone, that the influence of remedial measures can be reckoned on with any thing like confidence. It may be said that at so early a period we can have no certainty of the disease being actually incipient hydrocephalus; in dubious cases, however, it is infinitely more reasonable to assume the affirmative, and take our measures as if the presence of this formidable affection were fully ascertained, than to remain inactive spectators of its progress till the disease has assumed an unequivocal and comparatively hopeless character. When a family has already lost one or more of its number by this disorder, the recurrence of a precisely similar set of initiatory symptoms in any of the remaining children renders an active mode of proceeding doubly incumbent. Under the head of prognosis it has been already stated that cases in every stage of the disease have, under active and judicious modes of treatment, been brought to a favourable termination; and this is sufficient to show that trifling in the commencement, or despondency and the want of energy and perseverance to which it gives rise in the advanced stages of the complaint, are equally unjustifiable. There is too much reason to apprehend that many children have fallen victims, not so much to the incurable nature of their case, as to the indecision of their medical attendant.

The precursory stage being very commonly marked by derangement in the action of the intestines, and interruption or perversion of the biliary secretion, the employment of active purgatives, of which mercury should form a part, is almost always indicated; and we should persevere in their use with the double object of rendering the evacuations natural, and relieving the uneasiness in the head.

Where the threatening symptoms have taken their rise soon after an injury of the head, though it may have been of a slight nature, and the effects be as yet trifling, the employment of venesection, or the application of a few leeches to the temples as a precautionary measure, is advisable, in addition to the use of aperients and a reduction of the ordinary diet.

Where the symptoms in the head undergo no favourable change, though the bowels have been freely acted on, the probability of disease having become established within the brain becomes hourly stronger, and more energetic measures must immediately be had recourse to. The chief indications in hydrocephalus are to reduce the force of the cerebral circulation; to obviate all sources of irritation, whether originating in the abdominal organs or elsewhere, which might re-act on the brain, and thus aggravate, if they did not give origin to, the disease; to alleviate pain, vomiting, and convulsions, even where we fail in

removing their cause; to support the strength in the advanced period of the disease; and finally, when death seems inevitable, to render its approaches as easy as possible. For fulfilling the first and most important of these indications, our chief resources are to be found in the antiphlogistic class of remedies. Bloodletting, active and repeated purgation, cold applications, mercury, and blisters, are amongst the most accredited remedial agents, and are here arranged nearly in the order of their relative efficacy. The mode of employing these, as well as some additional therapeutic means, remains to be considered.

Bloodletting.—The advantage of early bloodletting in hydrocephalus is more generally agreed upon than that of any other measure whatsoever. The importance of the brain to all the functions of life, and the unyielding nature of the parietes of the cavity in which it is contained, show us, when conjointly considered, how the effusion, which in many other situations is the natural cure of inflammation, must within the cranium, if it proceed to any extent, be attended with extreme danger. The only safe termination to inflammation here is in resolution; and to effect this, free, early, and in some cases repeated abstraction of blood must be had recourse to. Opening the temporal artery, or copious venesection, either in the arm, or perhaps better still, in the jugular vein, often affords immediate relief to the headach, reduces the fever, and causes purgatives and mercurials to act with greater readiness and efficacy. Dr. Rush practised bleeding in this disease at least as largely as in phrenitis; and the activity of his practice has been equalled or surpassed by that of Dr. Maxwell of Dumfries, with the remarkable result of sixty recovering out of ninety cases, or two-thirds of the whole. The child being placed in the horizontal posture, Dr. Maxwell opens the jugular vein, and stops it from time to time with the finger, so as to prevent syncope taking place, till a very considerable quantity of blood has been obtained; the bleeding is allowed to go on till the pulse altogether disappears: a state of insensibility ensues, and occasionally continues for some hours afterwards. The disease is said to be often immediately arrested by the shock which is thus given to the circulation. But the possibility of death occurring under the very hands of the operator will probably prevent most persons from imitating this bold proceeding: besides, some doubts might be raised even as to the principle on which it is performed being physiologically correct or universally applicable, as excessive losses of blood are known, as already stated, to induce convulsions and effusion even in healthy subjects. The experience of no single individual, however extensive it may be, is sufficient to establish the propriety of such a practice; and certainly the great debility which exists in so many cases of hydrocephalus, seems often strongly to counter-indicate such an extreme measure. Except when the attack is of the very violent kind, with high fever, a strong pulse, and extreme pain and restlessness, the majority of practitioners are satisfied with a

single bleeding, and trust subsequently to the repeated application of leeches or to cupping. Cheyne is an advocate for early bloodletting in most infantile fevers of a suspicious character, attended with great irritability of stomach, tumid hypochondria, or suppression of the secretions. He has also adduced evidence of the utility of a moderate bleeding even in the advanced period of hydrocephalus, when pain of the head and vomiting continue to be predominant symptoms; at the same time he is convinced of the inadequacy of this measure singly to subdue the disease at any period of its progress, and believes that its repetition is even at times not unattended with hazard. The pulse must, however, be our guide, as, if it rises in strength, and the symptoms continue or recur, blood may again be abstracted with safety and advantage. By Abercrombie also, venesection is employed in the most decided manner in the acuter forms of the disease; whilst he admits that in those which assume a more chronic character, it has much less control over the disease, and cannot be borne to the same extent. Bloodletting seems to have been practised in some of his cases, and with occasional good effect, even after the occurrence of the slow, varying, and weak pulse of the second stage. The French practitioners generally trust almost exclusively to the free abstraction of blood in the earlier stages of this complaint; and some of them prefer taking it from a vein in the lower extremities, instead of from the arm or jugular vein; but we are not aware that any decisive proofs of the superiority of this mode of bleeding, which is gone into very general disuse in our own country, have been adduced.

Bloodletting has, however, its opponents as well as its advocates, but they are comparatively few in number. Dr. Garnett was averse to the employment of general bloodletting in children labouring under hydrocephalus; and even in adults he usually gave the preference to the local abstraction of blood, both because it appeared to him to exert more influence over the local inflammation, and because he thought it less likely to add to the debility which comes on in the course of the disease. Similar views of the relative value of local and general bloodletting are entertained also by Dr. Porter of Bristol. Such is not, however, the general opinion of the profession; and on a review of such cases as have fallen under our own observation, we have sometimes seen cause to regret that general bloodletting had not been earlier performed, or carried far enough, but never the reverse. That this as well as every other measure will, in a very great proportion of cases, prove ineffectual, we readily admit, as we do not participate in opinion with those who think that hydrocephalic inflammation is always as capable of being subdued by active antiphlogistic treatment, as that induced by injuries of the head in adults, which usually falls under the care of the surgeon. The predisposition and debility of constitution which often exist in the former, render the cases, in many instances at least, widely different.

As to the quantity of blood which may be

taken from infants with safety, the most specific directions are those furnished us by the late Dr. John Clarke: his extensive experience led him to the important conclusion that very young children bear well the loss of blood even to fainting, once or twice repeated; whilst on the other hand their powers are apt to sink if it be more frequently had recourse to. Children of four years old and upwards can, however, support the repeated performance of venesection with impunity. In infants of only a year old the jugular vein may often be opened without difficulty. At this period of life three ounces may be considered a full bleeding, and nearly the same quantity may again be taken away in twelve hours afterwards, if the symptoms seem to demand it, and the weakness is not too great. Where blood could not be obtained from a vein, Dr. Clarke gave cupping from the nape of the neck the preference to leeches. Local and general bloodletting should usually go hand in hand. Where the latter measure is, from the age of the child or any other cause, inapplicable, or has already been carried as far as is prudent, it is to cupping from the nape of the neck or to leeches that we must chiefly trust. For an infant of six months old, from four to six leeches, according to the strength of the child and the violence of the symptoms, may be once or oftener applied either to the temples or behind the ears, to the angle of the jaw, or to the nape of the neck; perhaps the latter situation, from its proximity to the medulla oblongata and base of the brain, may deserve the preference. Kuhn recommends their application to the inner angle of the eye, probably with a view to more directly unloading the cerebral vessels. When there is pain, tenderness on pressure, or fullness in the region of the stomach or liver, the application of leeches to these parts should not be neglected.

Purgatives.—Remedies of this class are exhibited in hydrocephalus with the double view of improving the secretions of the mucous membrane and liver, and thus removing one evident source of irritation, and also of producing derivation from the head, and diminishing the quantity of the circulating fluids. By means of calomel given in combination with jalap or compound powder of scammony, or, if these are found to irritate too much, with rhubarb, we shall generally succeed in procuring evacuations. At first these medicines may require to be aided by the occasional interposition of saline purgatives with the infusion of senna, which have the additional advantage of producing abundant watery secretions. Purgings actively seems to Abercrombie to be the remedy which is of the most importance in all the forms of the disease; and though he sets a due value on the aid of venesection, he believes that more recoveries from head affections take place under the use of very strong purgatives than under any other mode of treatment whatever. He has found the croton oil one of the most convenient and effectual cathartics in diseases of this kind, which are so often accompanied by great obstinacy of the bowels. Whytt never saw

even temporary relief of the symptoms produced by any other means than those which increased the evacuations; and Rush was likewise a strenuous advocate for the employment of medicines of this kind. It is chiefly at the commencement of the disease that active purgatives are proper; but even here there are limits and exceptions to their use. Where there is a high degree of irritability of the mucous membrane of the stomach or intestines, they will be useless or even injurious till these states have been subdued by blood-letting in some of its forms. When in a high state of excitement, we shall often attempt in vain to force the secretions of the liver or mucous membrane; and to procure healthy evacuations under such circumstances is quite out of the question. When the usual purgatives seem to aggravate the vomiting without moving the bowels, or when they produce only mucous stools attended with much irritation, a perseverance in their use cannot fail to be prejudicial. When the commoner purgatives have been rejected by the stomach, or proved insufficient, Dr. Cheyne occasionally succeeded in quieting the stomach and procuring evacuations, by giving a drachm or two of magnesia saturated with lemon juice every second or third hour, venesection to an adequate extent having been usually premised. In other cases he postponed the use of aperients till the state of the secreting organs had been first modified, and some appearance of feculent matter could be observed in the stools, under the influence of a combination of calomel, opium, and antimony. Besides, we must always bear in mind that the local irritation which the excessive or untimely employment of cathartics is capable of producing, cannot fail to re-act on the head, and aggravate instead of relieving the hydrocephalic symptoms. So great, however, is the torpor of the intestinal canal in most instances, that such cases are, perhaps, only to be looked upon as the exceptions. We cannot agree with Dr. Porter in condemning active purgation as an inefficient measure, even were his hypothesis granted, namely, that the derangement of the abdominal organs is always secondary, and merely symptomatic of the cerebral disorder.

Purgatives should have a fair trial in conjunction with other antiphlogistic measures during the commencement of the disease; after which, if they do not appear to be making any decided impression on it, the mercurial plan of treatment may be resorted to, a laxative enema or an aperient medicine being still occasionally exhibited. A large glyster of broth, with some of the purgative salts in solution, repeated frequently in the course of the day, has been found a useful palliative by Cheyne, the child lying at ease for a considerable time after its exhibition. Its good effect is attributable partly to its soothing influence, and partly to its protecting the intestines from the irritating qualities of the morbid fæces.

Cold applications.—The increased activity of the circulation within the brain may be

controlled in a considerable degree by the long-continued application of cold to the shaven scalp, which may be effected either by means of cloths kept constantly wet with cold water, or evaporating lotions containing spirits and ether; or more effectually still, by means of a bladder containing pounded ice mixed with water, kept in constant contact with the forehead, temples, and upper part of the head. This measure, in conjunction with an erect position of the head and trunk, persevered in for many days together, has been known to exert a surprising influence over inflammation of the brain both in adults and children. But the most efficient method of all consists in directing a stream of cold water against the crown of the head, and continuing it for some moments, till its full effect is produced. This is so very powerful a means of reducing cerebral action, as to demand much circumspection in its employment; and it is chiefly applicable to the more violent examples of the disease. To Burns it appears a measure of rather doubtful propriety, as it is often followed by alarming collapse: he thinks that it is only in the early part of the disease, when there is much heat, and when adequate evacuations have been already premised, that its employment can be safe. Abercrombie, while he admits that its use requires discretion, is a strenuous advocate for its utility in hydrocephalus, and has likewise employed it with great success in sudden coma connected with congestion of the head, and in the convulsive affections of children, in which last it is more effectual and much more generally applicable than the warm bath. Dr. Darwall has known cases which seemed utterly hopeless recover by letting water drop in a small stream upon the scalp, and continuing it till the head no longer recovered its high temperature on intermitting the stream; and Forney thinks it, when repeated every two hours for several days and nights consecutively, the most effectual remedy we possess both in the inflammatory stage and in that of effusion.

Mercury.—It is now nearly fifty years since the first recommendation of mercurials in hydrocephalus by Dr. Dobson; but though they have formed a part of the standard treatment of the disease during all the intervening period, the mind of the profession is still far from being made up, either as to the principle on which they act, or even as to their utility. Upon an extensive examination of the subject, the preponderance of evidence seems to be decidedly in favour of their employment. To bring the constitution of young children fully under the influence of mercury is often very difficult, and especially so in this disease; and even when we have succeeded, and the gums and salivary glands have become affected, the case too often runs rapidly on to its fatal termination. A few cases, however, seem unequivocally to have been saved by this remedy; and in many the convulsions and other symptoms have been rendered milder by it, and the senses restored, though the disease has not been eventually arrested, or the patient has been too weak to rally again. The effect of

mercury in controlling inflammation and modifying the action of the exhalents in other parts of the body is notorious; and in certain affections of the eye, as every step in the progress of improvement is exposed to view, there can be no doubt as to the reality of its influence. Its first introduction into the treatment of hydrocephalus was grounded on the hope of increasing the activity of the absorbents, and cases have since been recorded where it seems incontrovertibly to have had this effect. Thus in a young child labouring under the disease, where the sutures were not yet closed, Dr. Clarke has seen the fluctuating tumour at the fontanelles gradually disappear under the use of mercury; and numerous instances of recovery by the same means in very advanced periods of the affection, in some of which effusion had in all probability occurred, are favourable to the same hypothesis; as is likewise the influence which it seems occasionally to exert in cases of chronic hydrocephalus.

Considerable embarrassment is often felt as to the precise period at which the mercurial treatment should be commenced. To lay down any invariable rule as to this or any other part of the management of a disorder which appears under so many different forms, is impossible; but to give this practice a fair trial, it must be commenced before the inflammatory stage is very far advanced; and as we are often not called in till the disease has already existed many days, it is frequently necessary, after merely clearing out the bowels and abstracting a due quantity of blood, to proceed immediately to the use of mercury.

Calomel is the preparation usually employed. It may be given in doses of one or two grains, with or without opium, according to the state of the bowels and other symptoms, and is to be repeated every third or fourth hour till the gums become affected, unless griping and diarrhoea be induced by it, in which case the hydrarg. cum cretâ, or the external use of mercury should be substituted. Gölis, though he has great faith in calomel in the commencement of the inflammatory stage and previously, is averse to the large doses usually given in England, as he thinks he has seen them in some instances produce fatal enteritis, both in this disease and in croup. The dose to which he confines himself is half a grain repeated every two hours, till it produces four or five green slimy stools or colic; and after these effects have ceased, he returns to it again. If the bowels are very hard to move, he combines with it three or four grains of jalap previously toasted, in which state it is less apt to sicken or gripe. Children under one year he finds bear larger doses of calomel without colic, diarrhoea, or salivation, than those several years older. His experience here coincides with that of Dr. Clarke, who never saw salivation induced in children under three years of age save in three instances, though he employed it largely in a variety of diseases.

The corrosive sublimate in minute doses has been preferred by some practitioners when it is necessary to produce the specific effects of

mercury very rapidly. Dr. Merriman, who has succeeded in curing two cases of the disease with this preparation, employs it in doses of from one-thirtieth to one-sixteenth part of a grain repeated every four or six hours, with the effect of producing copious olive-green stools, and an increase in the urinary secretion.

In very urgent cases both the internal and the external employment of mercury should be combined. From half a drachm to a drachm of mercurial ointment may be rubbed into the thighs, or in very young infants more conveniently into the back, three or four times a day; and it may also be used as a dressing to blistered surfaces. If in the case of infants this ointment be objected to, calomel may be rubbed into the gums, three or four grains at a time, and repeated every four or five hours.

In whatever form mercury is employed, it is usually requisite to continue its use for a great number of days uninterruptedly; and when either it or any other medicine has produced a favourable change in the disease, its employment should never be abruptly terminated, but on the contrary very gradually relinquished. The only exception, perhaps, to this rule is in regard to digitalis.

Blisters.—The greatest contrariety of opinions prevails as to the period at which blisters should be used, and the place where they ought to be applied. If employed at all in the commencement of the disease, while the inflammatory symptoms continue high, a practice the propriety of which there is much reason to doubt, it should only be to parts at a distance from the disease, as the legs or arms, or between the shoulders, with a view to producing derivation from the seat of the inflammation. In the acuter cases, where there already exist much restlessness and vascular excitement, they can scarcely fail to be injurious till the activity of the circulation has been reduced by adequate evacuation.

In the second stage of the disease, a remarkable alleviation of the symptoms is frequently produced by the application of large blisters to the head or nape of the neck: a number of these may be applied in rapid succession to the vertex and all round the head; or what is perhaps a still more effectual method, the blistered surface may be kept in a state of supuration for several days consecutively, by dressing it with ointment of savin or of Spanish flies. The dread of strangury has deterred many practitioners from the use of the latter, though perhaps without sufficient reason, as it is possible that the occurrence of such an effect might occasionally even have a beneficial influence on the disease in the head. Tincture of cantharides has been exhibited with the very intention of inducing this species of irritation in the neck of the bladder by Dr. Merriman, in doses of five or ten drops every four hours, and the occurrence of severe strangury has appeared to him to arrest the cerebral symptoms; thus exemplifying the influence of a new and artificially excited disease in controlling the morbid action existing in a distant organ.

When tenderness in the epigastric or hypochondriac regions continues even after leeching the part, a blister may be applied here also with advantage. Gölis thinks that from the sympathy of the head with the stomach, a blister over the latter organ exerts a peculiarly marked influence on the cerebral symptoms; but as blisters often rise but slowly in this situation, he generally applies them in preference to the calves of the leg.

We have thus past in review those remedies which seem most entitled to confidence in attempting the cure of hydrocephalus. Of these, purgatives, bloodletting, and cold applications belong, as we have seen, more peculiarly to the early or most inflammatory period of the disease—mercury and blisters to the more advanced stages. But the stages often run into each other by such insensible steps, or are so completely confounded together, as frequently to render any division of this kind of very little avail in practice. It remains to say a few words of some other modes of more equivocal efficacy, or which are useful only as palliatives.

Digitalis.—This medicine, first used in this disease by Dr. Withering, and very generally employed since, is given in the earlier stages with a view to aid in reducing inflammatory action, and in the later to favor the absorption of the effused fluid. It is in that variety of the disease which succeeds to scarlatina, that it has appeared to be of most use. It is not, however, without difficulty that we can ascertain when it has been carried as far as is consistent with safety; for in consequence of the irregular state of the pulse, the tendency to vomiting, and derangement of the cerebral functions which already exist as a part of the disease, we are deprived of some of the chief signs by which to recognise the influence of the medicine. What we have seen of its use in this disease has not disposed us to value it highly. Dr. Cheyne, however, speaks rather favourably of it, and has given two cases in which it seemed to be of use. He begins with ten drops of the tincture, and to every succeeding dose, which is generally given after an interval of four hours, he adds two or three drops more than was contained in the preceding one; so that in a day or two some part of the system may be affected. He has thus given as many as one hundred and twenty drops a day to a child only four years old. He thinks that the slow irregular pulse from digitalis may be distinguished by its smallness and sharpness from that of hydrocephalus, which is not only unequal, but more soft and full. "The languor from digitalis is attended with vertigo, and sometimes with *momentary* blindness; that from hydrocephalus has more of coma in its character." Gölis, without appearing to place much faith in its efficacy, gives digitalis both in the inflammatory stage and in that of effusion—in the latter chiefly as a palliative to moderate the violence of the convulsions. He employs it sometimes in the form of infusion, and sometimes in that of the powder, in doses of a quarter of a grain, com-

bined with half a grain of calomel, repeated every second hour. He has not found it exert much influence on the urinary secretion in this disease. Some continental practitioners prefer extensive frictions made with the tincture of digitalis (sometimes combined with that of squills) to its internal employment. In whatever form it is used, if the pulse suddenly become very feeble, irregular, and slow, with increase of vomiting, and frequent recurrence of dimness of sight or blindness for a minute or two at a time, its use should be immediately intermitted, and stimulants, wine, soup, &c. substituted.

Antimony.—The late M. Laennec succeeded thrice in curing acute hydrocephalus by means of the tartrate of antimony given after his peculiar method. In two of them the disease supervened in the course of a continued fever. The subject of the third was a young man, who, after having sat up nightly in attendance upon his sick master for nearly four months, was seized with occasional vertigo and other symptoms which excited suspicion of some incipient cerebral affection. Some time after this he suddenly dropped down insensible, and after continuing in this state five days was brought to the hospital, where Laennec found him pale, motionless, and with the pupils greatly dilated. Leeches were applied to the temples, and twelve grains of the tartrate of antimony were given in the course of twenty-four hours. The next day he was able to move, and uttered some incoherent words. Fifteen grains were now ordered, and on the third day he had completely recovered his consciousness and power of motion, and the pupil had nearly regained its natural dimensions. He was still very feeble. As he had had no evacuation, eighteen grains of the tartrate were prescribed, and some nourishment. On the sixth day he was in a state of rapid convalescence; and crying out for food. Subsequent trials of this plan of treatment have not, we believe, tended to confirm the expectations which these cases (which by the way do not appear to have been very well marked examples of the disease) had raised.

The late Dr. Mills was in the habit of giving rather large doses of the tartrate of antimony, with a view to lower the pulse and relieve the headach; combining it, when the stomach was very irritable, with the tincture of opium. James's powder is, however, the preparation which has been most frequently used; small doses being given either alone, or oftener in combination with calomel, or calomel and opium, or with cathartics, with a view both to directly reducing the inflammatory action in the brain, and to assist in restoring the secretions of the abdominal organs and of the skin. This method of giving antimony is favourably spoken of by Dr. Cheyne. It has also been administered empirically in very large doses, so as to induce profuse perspiration, and it is said at times with success: in the hands of regular practitioners, however, this mode of giving it has failed entirely.

Opium.—In the second and third stage of

hydrocephalus considerable benefit has resulted from the use of opium. It has appeared not only to relieve the pain in the head and calm the general irritability, but also to reduce the morbid irritation in the intestines, and thus lead to an improvement in the stools, to render the pulse fuller and less irregular, and the convulsions less frequent; whilst fortunately it seems in no respect to impede, but rather to favour the action of other remedies. From the eighth to the fourth part of a grain of opium, or three or four grains of Dover's powder, may be given every fourth hour, either alone or in combination with calomel and antimony; or else with hydrarg. cum creta if there be great irritability of the mucous membrane. The contraction of the pupil which ensues after the use of opium has been pointed out by Drs. Crampton and Cheyne as affording evidence of the remedy having been carried as far as is safe. Dr. Brooke has recorded a case in the *Transactions of the College of Physicians in Ireland*, where Dover's powder, in large and repeated doses, proved a very useful palliative. All agree that a moderate employment of opium does not interfere with the action of the bowels. When its use is once commenced, the patient must be kept steadily under its influence; as, if suddenly withdrawn, the symptoms recur with increased violence.

Squills, colchicum, and other diuretics, have been recommended in the advanced periods of the disease. When, however, the stomach is very irritable, we must be cautious in the use of medicines which might aggravate the vomiting, and thus increase the determination of blood to the head. Dr. Warren, indeed, was bold enough to use emetics in hydrocephalus, but in this he has had few imitators. The warm bath, which has in this country been occasionally found a useful auxiliary, is thought by Gölis to determine the blood still more strongly to the head, and thus aggravate the violence of the symptoms. M. Itard is an advocate, in the advanced stages of the disease, for the use of the vapour bath impregnated with vinegar, a powerful means of stimulating the surface and producing an abundant flow of perspiration. At an earlier period, when there is much reaction in the system, M. Recamier, on the other hand, has used the cold bath, and it is said with some benefit. Fomentations to the abdomen when pain is complained of there; stimulating pediluvia, or what is more convenient and equally efficacious, sinapisms to the extremities, are also frequently had recourse to. Tartar emetic ointment is recommended by Mills, especially in those cases which have succeeded to a repelled eruption. When applied to the extremities, it has sometimes appeared to produce a very useful derivative action. In a disease in which the unfortunate patient often lingers on for an unexpected length of time in a state of great apparent suffering, a state at all times distressing to friends to witness, and most so when no efforts are made to relieve it, the advantage of a variety of resources during the long and painful

attendance is obvious. Recoveries having occasionally taken place under circumstances which seemed utterly hopeless, the medical man who values his own reputation will not resign himself to absolute inactivity at any period of the disease.

Palliatives. When we fail in subduing the morbid condition of the brain which constitutes the disease, something may still be done in the way of alleviating symptoms, and, even when death seems inevitable, in rendering the steps which lead to it less painful. To enumerate all the measures conducing to these ends would be to repeat much of what has been already detailed. Thus moderate blood-letting, either local or general, according to the degree of strength remaining, will often, even in the advanced stage of the disease, afford considerable relief, without appearing in any degree to accelerate the progress of the disease. Opiates at the same period form an invaluable resource.

Vomiting may sometimes be temporarily stayed by effervescing draughts, to which a few drops of laudanum and ether are occasionally added with advantage. This symptom may also be frequently much relieved by the administration of laxative enemata, to which a nutritive quality may be at the same time imparted.

Convulsions can often be cut short by the affusion of cold water on the head, or even by sprinkling the face and chest plentifully with it; a measure which is at once of easier application, and more frequently successful, than the warm bath. The simultaneous employment of cold to the head and the warm bath is often very efficacious. Musk and zinc in large doses appeared to Odier to have considerable influence in controlling this symptom. When very violent and long-continued, the trial of an enema, composed of a very weak solution of tobacco, might perhaps be justifiable. For the mode of employing it, and its utility in an analogous instance, see GLOTTIS, SPASM OF. Where coma is the predominating feature of the complaint, strong coffee or tea have been given in the advanced period of the disease with some appearance of benefit. Retention of urine is often relieved by turpentine enemata or the hip-bath.

The diet in the earlier and more inflammatory part of the disease should be strictly diluent; but when it has already run on for a number of days, with rapidly increasing debility and emaciation, it becomes a very important object to support the strength. This is peculiarly necessary where the urine, perspiration, or any of the evacuations, has, either by a spontaneous effort of nature or under the influence of medicine, become unnaturally increased. Under these circumstances, beef-tea, jelly, asses' milk, &c. should be freely given. Life has sometimes seemed to be considerably prolonged in this disease under the influence of light stimulants and tonics, wine, small doses of ammonia, quinine, &c. Arnica is a favourite remedy with some German physicians:

we need not say how reluctantly and with how much caution such remedies should be had recourse to.

When recovery takes place, the convalescence is often very slow, and requires uninterrupted attention to the state of the bowels, and great care in the regulation of the diet. Asses' milk is here an invaluable article of nutriment, as it recruits the strength without exciting the pulse, oppressing the stomach, or confining the bowels.

If hydrocephalus supervenes in the course of an infantile fever, or in a child greatly debilitated by diarrhoea or other previous illnesses, the treatment presents peculiar difficulties. We are here often unable to venture on general bloodletting, and are obliged to trust to leeches, cold applications to the head, blisters, and calomel, to which opium is to be added if there be great irritability of the mucous membrane or nervous system. Such remedies certainly afford a fairer prospect of success than the *arnica*, *serpentaria*, and other stimulants recommended by Kuhn and some other German writers.

Where the head becomes suddenly attacked in a patient labouring under one of the exanthemata, nothing but the most vigorous antiphlogistic measures condensed into the shortest possible space of time can afford even a chance of safety. Venesection or arteriotomy, leeches, ice to the head, or a stream of cold water poured from some height on the vertex, purgatives by the mouth, or if the patient is unable to swallow, active enemata; and stimulating vapour-baths where the eruption has suddenly receded, or sinapisms or blisters to the extremities, should all follow each other in quick succession. The following case from Gölis gives some idea of the rapidly fatal nature of the attack. A child of two years old, on the fourth day from the eruption of scarlet fever, seemed to be going on favourably at eight o'clock in the evening. At midnight it became highly feverish and convulsed; spasms of the muscles of the back and palsy of the right side soon followed, and within ten hours it was dead. We have ourselves seen it fatal on the second day of the attack. Fortunately, however, this may be considered a rare form of the disease. That which occurs in the convalescence from scarlatina is much more frequent. It comes on with giddiness, headache, somnolence, and nausea or vomiting, to which convulsions and all the other symptoms of hydrocephalus are soon added. It demands the prompt employment of bloodletting and purgatives, blisters, and digitalis. Bark has appeared to Dr. Blackall to have much effect in accelerating convalescence.

Prevention.—Where there is reason to suspect a predisposition to hydrocephalus, as is the case with respect to the children of a family which has already suffered by the disease, and perhaps with regard to scrofulous children generally, the earliest attention should be paid to every deviation from the natural state of the functions of the body, and especial care directed to the condition of the digestive

organs. To support their tone and that of the whole system by good air, nutritious unirritating diet, and daily exercise, is a point of prime importance. Where costiveness exists, or the stools by their unnatural colour or consistence indicate derangement in the secretions of the liver or mucous membrane of the intestines, appropriate remedies should not be a moment delayed.

An issue or seton in the arm or neck has sometimes seemed to have a remarkable influence in warding off this disease. We know an individual of a family strongly predisposed to it, whose life appeared to have been saved by an issue long kept open in the arm. Though the eighth child of the family, he was the first who survived infancy, the seven older ones in whom this precaution had been neglected having all died of hydrocephalus. Dr. Cheyne, in the work to which we have been so frequently and so largely indebted, mentions some still more remarkable instances of the good effects of establishing an artificial irritation at some distance from the morbidly disposed organ.

The parents and instructors of children of a peculiarly precocious intellect should be made aware of the danger of early and protracted application. In such individuals it should be our object, if possible, rather to retard than to accelerate the development of the brain and of the mental faculties connected with it; and it is only by postponing the interests of their intellectual to those of their physical education, till the constitution has become established and the period of danger is past, that this object can be attained.

II. CHRONIC HYDROCEPHALUS.—This affection may be either congenital or acquired. When congenital, some malformation or defective development of the brain in many cases coexists. When acquired, it may either come on as the sequel to the acute form, which however is rare; or it may originate insensibly, and attract little attention till the functions of the nervous system and of the body generally become perceptibly deranged by the pressure of the effused fluid. In all its forms it is in the earlier stages of existence, while the brain is undergoing the process of evolution, that it chiefly occurs.

When the cranium becomes very much enlarged, as the face retains its ordinary dimensions, or is even smaller than natural, the visage assumes a singular triangular appearance, and the patient being unable to support the immense head, it hangs on one shoulder or on the breast. The sutures and fontanelles continue widely open, and pulsation of the arteries, as well as the fluctuation of the contained fluid, can be distinctly felt through them. Occasionally, from the unequal yielding of the brain and its membranes, a circumscribed tumour presents itself at some of these openings.

That the dimensions of the head are always increased is the popular belief; and Frank has included enlargement of this part in his definition of the disease. Yet this is far from

universally taking place, for the head is sometimes of the ordinary size, or occasionally even smaller than natural.

Gölis, the best writer on this disease with whom we are acquainted, and Breschet, who usually copies him closely, have divided the disease into three varieties, having relation to the size of the head. The first variety, or that in which the head is enlarged, is either congenital or commences in early childhood. The second, or that in which it is unnaturally small, is always congenital. The sutures are found closed at birth, and the head is of a conical shape. Such children are usually dead-born, or die in convulsions soon after they come into the world. Should they by chance survive a few months, their intellect is totally defective; they are blind, with the pupils greatly dilated, and the eyeballs in constant convulsive motion. They lie in a state of almost total insensibility, with their legs crossed and drawn up to the belly, their toes contracted and feet distorted. Of this variety Gölis has known but a single instance attain the age of eighteen months. The third variety, or that where the head is of the natural size, is perhaps the commonest of all, as it may take place at any period of life.

In chronic hydrocephalus the intellectual faculties, the senses, and the muscular power all suffer. The patients labouring under it become emaciated, and of a pallid unhealthy complexion, stupid and indifferent to external objects. The countenance is without expression. The senses become successively impaired, the sight being the first to fail. The gait is unsteady, as the power over the involuntary muscles is in a great degree lost.

The following abstract of the symptoms is chiefly taken from the second volume of Gölis's work, which has not, we believe, hitherto been translated into English.

When the disease comes on at a period subsequent to early infancy, its first approaches are commonly indicated by an unusual excitability of the nervous system. The individual is easily made to laugh or to cry by the slightest causes, is peculiarly irascible, and the temper and dispositions are totally changed. The memory is impaired or lost. The muscular debility is excessive. Epileptic fits, especially at night, are of common occurrence; and on awaking a peculiar piercing cry is often uttered. There is a great degree of sleepiness, together with a dull pain and heaviness of the head. By shaking the head, vertigo or complete stupefaction is brought on. If we make pressure on the fontanelles, a soporose state often accompanied with convulsions is induced. The pupil of the eye becomes larger and larger as the disease advances, and amaurosis usually takes place in the end. Squinting exists in some instances, whilst in others the eyeball oscillates from side to side. The sense of smell becomes perverted or lost. In the former case imaginary odours are complained of; and the nose is at all times itchy and dry. The function of hearing is also impaired. In short, the senses of taste and touch are often the only ones retained, and these occasionally in a very

imperfect degree. Violent grinding of the teeth, which are thus sometimes worn down to the stumps, is very common. If the patient possess the power of speech, it is for the most part nasal and snuffling, and often interrupted for want of words in consequence of the defective state of the memory. From the mouth, which is usually half open, the saliva is constantly dribbling, either from this secretion taking place in an excessive quantity, or from a diminished power of swallowing. Of the secretions and excretions the saliva and tears are the only ones which do not appear to suffer a decrease.

The functions of the digestive organs are considerably changed from the natural state. The appetite is often voracious; there is frequently a tendency to vomit, and obstinate constipation is rarely absent. The urine is diminished in quantity, and both it and the fæces in the advanced stages of the disease are passed involuntarily.

As the disorder advances, the pulse and respiration become affected, the patient sighs much, and is put completely out of breath by the slightest causes, and paroxysms of suffocative cough occasionally take place. Debility and loss of power over the voluntary muscles is one of the earliest symptoms, and is manifested in the unsteadiness of the gait. Automatic motions of the limbs are common. The posture is much influenced by the disease. When it has made some progress, the erect position of the body can often no longer be borne, as it causes pain in the head, with lightness and stupefaction, and inclination to vomit. There is usually a disposition to keep the head lower than the rest of the body, and not unfrequently a preference is manifested for lying on the belly with the face buried in the pillow. When they lie on the back, the head is often rolled with great regularity from side to side. In the last stage the patient lies gathered up, with the legs crossed and drawn up against the belly, the cervical vertebræ and head being thrown back, whilst the rest of the spine is bent forward. As the disease approaches its fatal termination, the pulse becomes weak, irregular, and intermitting, and the extremities cold and damp. Death takes place either by the superposition of the symptoms of acute hydrocephalus, or by a slow hectic fever, the scene finally closing either with a paroxysm of suffocative cough or with an attack like apoplexy.

Though the impairment of the intellect and senses usually keeps pace with the advancement of the disease, and the subjects of it at length may be said rather to vegetate than to possess an animal existence; yet a few cases are on record, where, though the head had attained to a very considerable magnitude, the individual continued perfectly rational and observant of things around him; whilst in other instances again, amidst the general wreck, some one faculty, as the memory for example, has alone escaped uninjured. The moral qualities usually suffer as much as the intellectual, the hydrocephalic patient being fre-

quently passionate and revengeful; and every time that a fit of anger is excited, convulsions are apt to follow.

The sexual propensities commonly continue strong, and in several instances, in children of both sexes, a remarkably premature development of the organs of generation has been observed.

Hydrocephalus being a disease of fetal life, and the unnatural-sized head often presenting a great obstacle to delivery, and frequently even requiring an operation destructive of the life of the child, its early detection would be very desirable. Unfortunately, however, till the head actually presents itself in the progress of delivery, we have no means of detecting its existence. The fact of the mother having previously borne hydrocephalic children should excite a suspicion of its existence in cases of difficult parturition.

The disease may take its rise either before birth or very soon after it, or more rarely during the later periods of childhood. Yet even adult age is not altogether exempt from it. Gölis has mentioned three cases where it came on in old age. Two of the individuals in question were above seventy years old. The third, who was a physician in Vienna, likewise died of it at a very advanced period of life, after having suffered from the disease ten years. In such cases, however, it rarely runs on for more than three years. In cases occurring subsequent to early childhood, no change in the external form of the head is appreciable, for the sutures and fontanelles in most children are found already closed in their second or third year. Occasionally, however, as we learn from Ruysch and Van Swieten, they remain open much longer. We know at present of a child of upwards of six years old, in which the posterior fontanelle is still open; it is of a scrofulous habit, but has hitherto manifested no tendency to hydrocephalus. Dr. Baillie met with a singular case in a boy of seven years of age, where the coronal and sagittal sutures, after having been firmly closed, reopened to the extent of half an inch and upwards from the pressure of the accumulating fluid. The same author has detailed an instance of chronic hydrocephalus occurring in a man fifty-six years of age, in the ventricles of whose brain six ounces of fluid were discovered. The chief symptoms were pain of the head, and a loss of memory so great that he could recollect but five words, which were continually reiterated to express all his wants. He seemed to retain somewhat of his intelligence. There was no dilatation of the pupils, and the sight was good. The pulse was occasionally rather quick, and never became either slow or irregular. The hemiplegia which existed was accompanied with a permanent rigid flexion of the paralytic limbs, like a fakir. Heberden, on the other hand, has mentioned the case of a man in the ventricles of whose brain, though eight ounces of water were found on dissection, no symptom of hydrocephalus had existed during life.

The duration of this disease is very various.

When it commences in utero, death almost always occurs very soon after birth; and if it originate in early infancy, the child very rarely survives the third year. Yet the brain in some instances becomes, as it were, reconciled to the pressure of the contained fluid, and existence has thence in a few rare cases been prolonged to adult age. Gölis mentions one in which the patient lived to twenty-seven; Aurivill another which reached forty-five years; and Gall one which attained to fifty-four years of age. In the case of Cardinal, who died in Guy's Hospital a few years ago at the age of thirty-two years, the head was of a great magnitude, being thirty-three inches and a half in circumference, and twenty inches and a half from ear to ear. Notwithstanding this immense enlargement, many of the functions of the body were little impaired. The appetite and digestion were natural, and his intellect not remarkably deficient. He was, however, subject to occasional epileptic attacks, especially when costive; and he was unable to walk much, as vertigo was speedily induced by it. For some weeks before his death he was somewhat comatose, though still capable of answering questions when roused: the insensibility gradually increased, and he sunk at length as if apoplectic.

Prognosis.—It is only in the early stage that much can be effected by medicine in this disease. If treatment be deferred till the head has become greatly enlarged, the case is too often hopeless. When it is congenital, or occurs very soon after birth, its termination is, according to the best authorities, invariably fatal. In other cases, Portenschlag, Dreyssig, Richter, and Gölis, think it may often be cured, especially if there be no complication, if the disease be early seen, and no great exhaustion has as yet come on. Frank looks upon the disease as very generally incurable. He knew of one case which disappeared on the invasion of a scrofulous affection in another part of the body; and both he and Gölis have seen the breaking out of chronic cutaneous eruptions and sores behind the ears have a very favourable influence over the disease. On the other hand, where any of the exanthemata supervene, speedy death is the usual consequence. Cases originating where there is a scrofulous or syphilitic taint, or after concussion or other accidents by which the texture of the brain may have been injured, have appeared to Gölis particularly unfavourable. Those which arise as a sequel to acute hydrocephalus are likewise very unpromising, as has been already stated. The same may be said of those cases where there is long-continued coma, furious delirium, or frequent convulsions from very slight causes.

Of the *causes* of this disease little is known with certainty. A strong predisposition to it undoubtedly exists in certain families. Thus Frank mentions the circumstance of a mother bearing seven children, all of which were born with this affection; and Gölis another, in which six of the children were born prematurely in the sixth month of pregnancy, labouring under chronic hydrocephalus; and in the three others,

which were carried to the full time, it appeared soon after birth. The father being very old or drunken, is thought by the last-named writer to predispose the offspring to the disease; and perhaps intemperance in either of the parents has a similar tendency. A scrofulous habit, and violence done to the head in birth, may also be numbered amongst the predisposing causes. Mechanical injuries, falls, shocks, and blows, are capable of exciting it; as is likewise the sudden repulsion of cutaneous diseases, the suppression of the menses, over-exertion of mind, and long-continued anxiety.

Appearances on dissection.—The bones, which are usually remarkably thin and transparent, are frequently separated from each other by a very considerable interval. When the patient has lived for several years after the commencement of the attack, nature often appears to make an effort to close the sutures by the establishment of new points of ossification and the formation of *ossa wormiana*. The thinness of the bones of the skull, though an ordinary, is not an universal appearance. They have sometimes, on the contrary, been observed of unnatural thickness, which, like the supernumerary bones above alluded to, seems to mark an attempt on the part of nature to counteract the effects of disease, and restore to the cranium a proportional thickness. It is supposed that such thick and large skulls on being dug up have been mistaken for those of giants, an error which attention to the comparatively diminutive bones of the face would have prevented. The head of hydrocephalic patients is sometimes of a very irregular form, one side being much more prominent than the other. The effused fluid is found either in the ventricles, or, though much more rarely, in the great sac of the arachnoid. In the former case the ventricles are extremely dilated, the convolutions are unfolded, and the brain converted into a thin membranous-like sac, in which the medullary and cineritious substance can no longer be distinguished. The corpus callosum is much raised, and the septum lucidum occasionally torn or destroyed, so that the brain has sometimes been found forming only one great hemisphere without any central division. The cerebral substance seems denser than usual, and its absolute quantity as compared by weight with that of a healthy individual of the same time of life, in many cases does not present any diminution.

When the water is contained in the sac of the arachnoid, frequently scarcely any appearance of brain can be discovered; or the parts constituting its base, the pons varolii, medulla oblongata, &c. alone exist.

With water in the head and imperfect development of the brain, malformation in other parts of the body frequently coexists. It is now a generally received doctrine that many congenital defects of structure depend upon the continuance of certain states belonging to the earlier periods of fetal existence beyond their proper time. Thus the fluid which naturally occupies the ventricles during the first steps of the formation of the fetal brain, by remaining

unabsorbed, may lay the foundation of congenital hydrocephalus.

A rare species of the disease is mentioned by Schmalz, in which the fluid is encysted. In such cases the sudden bursting of the sac has led to a fatal result. Gölis met with a cyst of this kind about the size of a goose's egg, situated between the hemispheres, in a child of six years old, who died suddenly, though the bag was in this instance entire.

The quantity of fluid discovered in the head varies from a few ounces to several pounds. Cases in which upwards of ten quarts have been found are on record. In the case some years ago in Guy's Hospital, to which we have already alluded, the bones of the cranium were found on dissection to be of an ordinary thickness. On cutting through the dura mater water immediately gushed out. This was of a pale yellow colour, and the total quantity contained within the head was found to exceed ten pints. At the bottom of the great cavity formed by the immensely dilated skull, lay the brain much flattened. The corpus callosum was defective, so that the ventricles of the brain communicated directly with the great sac of the arachnoid. This was, by some of those present, thought to be a natural malformation, as the convolutions of the brain were not unfolded and obliterated, as in those cases where the effusion takes place originally into the ventricles.

Dr. Baron, in the eighth volume of the *Medico-Chirurgical Transactions*, has given the history of a very interesting case of congenital hydrocephalus. At three months old the head had attained to the enormous magnitude of twenty-nine inches in circumference. About this time a swelling appeared at the posterior fontanelle, and soon acquired the magnitude of a goose's egg. This suddenly became much smaller and soft, and a constant dribbling from the urinary passage was observed, by which the head in three days became so reduced in size, and the integuments were so relaxed, that the skin of the forehead fell in wrinkles over the eyes. The urinary discharge by the end of two months diminishing, the swelling on the top of the head reappeared. A watery discharge tinged with blood now began to ooze from the nostrils and mouth, and flowed most freely when the head was held forward; by this the tumour was again reduced, and the circumference of the head brought down to twenty inches. The child died at eighteen months old. On dissection, the dura mater was found ruptured, a well defined circular opening nearly an inch in diameter existing in the situation of the tumor, and communicating directly with the interior of the brain. The brain itself, which was expanded into a great sac with very thin parietes, had likewise given way at this part, and thus allowed the fluid from the internal cavity to escape into the outward swelling. A probe passed easily through the æthmoid bone into the nose.

Treatment.—In this disease the unassisted efforts of nature seem incapable of effecting any thing. The indications consist in the re-

moval of the fluid already contained within the cranium, and in subduing the tendency to its further effusion; but unfortunately the resources which we possess will too often prove utterly unavailing towards the fulfilment of either of these objects. Diuretics, purgatives, and diaphoretics, together with mercury, tonics, and a strengthening diet, are the internal measures which, singly or conjointly, have been most confided in; whilst, externally, it has been recommended to keep the head warm, to apply aromatic and slightly stimulating embrocations, or to employ severer but more promising remedies, such as blisters, issues, tartar emetic ointment, and even the actual cautery. Local and general bloodletting have also frequently been had recourse to.

Gölis asserts that he has cured the majority of cases when early seen, provided they were not congenital or occurring very soon after birth, by the long-continued use of calomel internally, by the application of a mercurial ointment to the head, which is kept constantly covered with a woollen cap, and by the daily use of stimulating baths.

In more obstinate cases he has been obliged, in addition to these measures, to employ issues, blisters, or tartar emetic ointment to the head, and under particular circumstances leeches or cupping. In scrofulous habits a tonic plan of treatment must be carried on simultaneously with the above remedies. He has occasionally, also, called in the aid of mild diuretics or diaphoretics, and such measures as appeared to him best calculated to quiet nervous irritation, and to support the strength.

The remedy which has most frequently appeared useful is, unquestionably, calomel. This he gives in doses of half a grain twice a day; and if it purge too much, he reduces it to a quarter of a grain, or even intermits its use for a short time. Whilst employing calomel, one or two scruples of mercurial ointment, combined with an ointment of juniper berries, are rubbed into the head every night. The woollen cap, in which he has great confidence on account of its keeping up a constant though slight counter-irritation on the closely shaven scalp, and at the same time supporting the insensible perspiration, and preventing the sudden cooling of the head, is worn constantly for many months, and even then only very gradually laid aside. Becoming impregnated with mercurial ointment, it must help to bring the constitution more speedily under the influence of this remedy.

Mildly stimulating baths he conceives likewise to have a very beneficial influence, as they tend to excite an extensively diffused though moderate stimulus over the whole cutaneous surface. Alkaline baths may be employed for this purpose. Baths holding tartar emetic in solution, in the proportion of one ounce of this substance to a pailful of water, and gradually made three or four times stronger, have been found by M. Recamier a very useful remedy in this disease, appearing, whilst it reduced the size of the head, to

act as a diuretic, and render the patient thinner.

If in five or six weeks some improvement is observed, or if salivation takes place, the calomel and the ointment are to be used only every second or third day. During the whole continuance of the mercurial course an ascendent vegetable diet is to be avoided, as being liable, according to Gölis's experience, to cause colic and gastro-enteritis. Infants require no other nutriment besides good breast-milk, whilst for older patients a moderate quantity of flesh meat is proper. In mild weather they should both be much in the open air. Under this plan of treatment Gölis has known the circumference of the head decrease by from half an inch to an inch in a period of from six weeks to three months, and has frequently seen a perseverance in it effect a perfect recovery both of the mental and bodily powers. When the automatic motions of the limbs cease, and the patient becomes able to hold up the head, to sit up, and even to walk a little, we have evidence that a beneficial change is going forward.

If within two months, on the contrary, no improvement is visible, mild diuretics, such as the acetate of potass or squills, may be associated with the preceding remedies, together with an issue in the nape of the neck, or in both arms, kept open for many months; or tartar emetic ointment, or blisters to the same parts, so as to keep up a steady discharge. The use of these measures is particularly indicated when the disease has supervened on the sudden disappearance of a cutaneous eruption. We have known large blisters, applied alternately to each side of the head for many weeks in succession, productive of much benefit. Convalescence, according to Gölis, may be much accelerated by minute doses of the sulphate of quinine, as a quarter of a grain thrice a day.

If acute inflammation of the brain or its membranes supervenes, the antiphlogistic plan of treatment must be put in practice; leeches, calomel in larger doses, blisters to the calves of the legs, &c. Even in the later period of the disease, when hectic fever has come on, the symptoms have been moderated and life prolonged by leeches and calomel.

The palliative treatment recommended by Gölis in the advanced and hopeless stages, consists in such medicines as tend to promote the secretions, and to moderate convulsions, viz. aperients, diuretics, and antispasmodics.

As to the propriety of evacuating the water by means of an operation, where all other means have failed, practitioners have long been divided in opinion. Gölis has given the names of twenty-seven writers who have expressed themselves in favour of it, especially if the fluid be slowly evacuated, and at several repetitions of the operation. Yet he himself along with seven or eight others, including Boerhaave, Heister, Hecker, and Portenschlag, proscribe it altogether as cruel and useless. Richter thinks, that even where the water is gradually

drawn off, death by the disease always sooner or later ensues; and Gölis asserts that the fatal termination is even accelerated by it. It appears to us, however, that he has spoken too decidedly on this point, as there are a few cases on record where it has appeared to effect a cure, and several where it has palliated the symptoms. In cautious hands, and where only a moderate quantity of water is drawn off at a time, it has rarely been attended with any immediate danger. In cases where all other kinds of treatment have been tried without benefit, this is, perhaps, not altogether to be rejected.

In a case related by Dr. Vose of Liverpool, in the *Medico-Chirurgical Transactions*, this operation was performed with complete success on an infant seven months old, when the head was more than double the natural size. The instrument used the first time was a couching needle, and the quantity of fluid drawn off upwards of three ounces; about as much more was supposed to have dribbled away afterwards, upon which the child became very weak, but revived by means of the moderate administration of slight cordials. About six weeks after, the water having re-accumulated, an opening was made with a bistoury, and eight ounces were again taken away; and by a third operation nine days after the second, twelve ounces were drawn off without any injurious effect on the general health. A copious serous diarrhoea now set in, by which considerable debility was induced, but this was only temporary. The head gradually diminished in size, and the patient completely recovered.

Mr. Lizars has detailed a case in the *Edinburgh Medical and Surgical Journal*, in which he operated about twenty times in the course of three months. The instrument which he usually employed was a delicate trocar, which was introduced at the most laferal part of the anterior fontanelle, so as to avoid the longitudinal sinus, and thrust in to the depth of about one inch below the surface of the integuments. On the reduction of the water the strabismus and dilatation of the pupil ceased immediately. In some of the later operations, the sutures having become in part closed from the progress of ossification, the head was no longer capable of being adequately compressed, and air rushed in to supply the place of the extravasated fluid, but without any ill effects ensuing. The case proves, if not the utility of the operation, at least its safety, when carefully conducted. About the same time with the above case, another was published in the same journal by Dr. Freckleton of Liverpool, in which the lateral ventricles were four times punctured with safety; but in the fifth operation, fourteen ounces of fluid being taken away at once, the child became very uneasy and convulsed, and died on the ninth day.

More recently the operation has been repeatedly performed, and with very favourable results, by Dr. Conquest of London, to whose kindness we are indebted for the following particulars. The total number of children on

whom he has operated is nine, and in four of these the operation has been completely successful, the individuals being now quite healthy and free from every symptom of their former complaint. The largest quantity of fluid withdrawn at any one time has been twenty ounces and a half; and the greatest number of operations on one child has been five, performed at intervals varying from two to six weeks. The largest total quantity of water removed was fifty-seven ounces by five successive operations. The trocar was introduced through the coronal suture, below the anterior fontanelle; and pressure on the head was subsequently made by strips of adhesive plaster, with which likewise the wound in the integuments was carefully closed after each operation.

The first successful case was operated on before a large number of medical men at St. Bartholomew's Hospital in the session of 1829. Of this, and a subsequent one, a short account appeared in the *Lancet* in April and November, 1830, to which we refer the reader for further information.

Puncture has likewise been lately had recourse to with complete success by the celebrated Graefe* of Berlin, in the case of an infant whose head, of preternatural dimensions from birth, had attained to a great magnitude at the age of four months, when the first operation was performed: no derangement in the functions of the body had, however, as yet manifested itself. The operation was repeated eleven times within the course of six months. The fluid was each time allowed to escape only slowly and interruptedly; and the canula was altogether withdrawn and the wound closed as soon as the pulse was observed to become weak, the pupil contracted, and the expression of the face altered, symptoms which, under the influence of stimulants, always disappeared within a few hours after the operation. Each operation was followed by a considerable diminution in the size of the head, and after the eleventh and last the sutures closed. The child could walk and speak before it was a year old. At the age of two and a half (upwards of a year and a half after the completion of the cure,) it was exhibited at the Medical Society of Berlin.

A still more recent instance of the value of this operation has been put on record by Mr. Russel of Edinburgh.† At three months old the head of his patient had attained to an enormous size, (twenty-three inches in circumference, and fifteen inches and a half from ear to ear.) There was strabismus and constant rolling of the eyes, irregularity of the bowels, and frequent starting in sleep; but the pupils were neither dilated nor insensible. Compression, blisters, mercury, diuretics, &c. having already been tried without the slightest benefit, recourse was had to puncture as the last resource. By four operations performed at

* *Graefe and Walther's Journal für Chirurgie*, &c. 1831, b. xv. p. 3.

† *Edinburgh Med. and Surg. Journ.*, July, 1832.

intervals of about ten days, the dimensions of the head were considerably reduced. After the fourth operation, the water again threatening to accumulate, calomel was administered in small doses, so as to affect the mouth, by which all the remaining hydrocephalic symptoms were removed, and the cure confirmed. The size of the head at eight months old was found to be less by four inches in circumference and two and a half across the vertex, than it had been previous to the first operation; and the ossification of the sutures was complete.

Storch has mentioned an instance of hydrocephalus where the spontaneous escape of about a pint of serous fluid by the nose was followed by temporary relief; and a singular case has been related by Mr. Greatwood, where a child of fifteen months old was accidentally cured of the disease by falling upon the back of the head upon a nail, above three pints of fluid gradually escaping from the puncture thus made.

When the operation of puncturing the head is followed by extreme faintness and collapse, as is occasionally the case when too much fluid is removed at once, small doses of ammonia, or a few tea-spoonsful of brandy and water, may be given to revive the patient. Inflammatory reaction sometimes sets in within the course of a day or two. Here leeches, cold applications, aperients, and other antiphlogistic measures must be employed.

Sir Gilbert Blane, conceiving that chronic hydrocephalus might sometimes depend on a want of firmness and due resistance in the bony compages of the skull, tried the effect of compression by means of a roller, with apparent benefit, in a case related in the Medical and Physical Journal for October 1821. But as leeches and purgatives were simultaneously employed, it is very difficult to say what share the compression had in the amendment which took place. Mr. Barnard has related two cases in the Medical Repository, in which pressure on the head made by means of straps and adhesive plaster, along with leeches and the application of cloths wet with cold water constantly to the head, appeared beneficial. In other hands, however, compression has failed altogether.

(W. B. Joy.)

HYDROPERICARDIUM.—From ὑδωρ, *aqua*, and τὸ περικαρδιον, (*th. περί et καρδία*.) *pericardium*. *Hydrops pericardii*, *dropsy of the pericardium*.—This affection can very rarely require the exclusive attention of the physician, since, although the pericardium is frequently the seat of effusion, it is seldom, probably never, so affected independently of organic disease either of the heart or some other structure. The symptoms consequently are always more or less obscured by the concomitant affections; and even when we are enabled to attain a tolerable certainty of the presence of fluid within the pericardium, its removal alone would have but little effect in restoring the patient to health. These and some other considerations of a similar nature

might almost induce us to exclude hydropericardium from a separate consideration, but as it has usually obtained from nosologists and writers on the diseases of the heart a distinct place, it could scarcely be omitted in a cyclopædia of medicine. The treatment of the subject is, however, a matter of very considerable difficulty, and the information we have to offer must be rather of a negative than a positive kind.

As the pericardium is a serous membrane, and hence always in some degree bedewed with moisture, a preliminary enquiry becomes necessary as to what must be considered its natural state, and what quantity of fluid ought to be regarded as constituting disease. This question has been much discussed by older authors, while the more modern have been usually content to refer to the opinion of Corvisart, without inquiring into the data upon which that opinion was founded.

Among the ancient authors, Vesalius and Lower maintained that the pericardium generally contained some fluid, and the former had observed it in the pericardium of criminals, who had been quartered while yet alive. He was not, however, certain of its existence in every case. Lower says decisively that some fluid is always present, but without any detail of the researches which led him to entertain so positive an opinion. Hoffmann, after referring to these and other authorities, merely observes that he had never been able to detect any fluid in the pericardium of animals which he had opened alive. Haller, after reviewing these and many other writers, intimates that in his opinion some fluid, but in very small quantity, is always to be found, and that it does not usually exceed a few drachms. Littré had decapitated puppies, and had always found some water in the pericardium. Senac, reviewing these contradictions, and remarking that in a number of bodies in which the heart and its envelopes were perfectly natural, the membrane was dry, inclines to the opinion that in the healthy state the pericardium contains no fluid, but at the same time admits that some fluid is occasionally observed which could not properly be referred to disease. Corvisart does not enter at any great length into the dispute, but contents himself with pronouncing, that whenever the fluid exceeds six or eight ounces in quantity, it must be regarded as the effect of disease, and consequently as forming hydropericardium. To this last author Kreysig, Bertin, Testa, and other contemporary writers are satisfied to refer, and in this state the subject still rests. Under these circumstances we have endeavoured in some degree to promote our knowledge of this subject by the result of dissections, and the following tables will shew what proportion of one hundred and fifty examinations exhibited fluid in the pericardium. Fifty of these cases are drawn from our case-book; fifty, respectively, are furnished by Mr. Wickenden and Mr. Parsons of Birmingham, who are well qualified for such investigation. Any appreciable quantity of fluid was always noted, that is, whenever it exceeded a couple of drachms; in some cases even less than this

was noted. To this we shall add an additional table of sixty-four cases, for which we are indebted to Mr. Baynham, whose pathological researches have been very extensive, and are most valuable from the accuracy with which they have been conducted.

I. *Table of one hundred dissections, with the number of cases in which water was found in the pericardium.*

Nature of the disease.	Total number of cases.	Number in which there was water in the pericardium.
Laryngitis.....	2	
Bronchitis.....	12	3
Typhus and synochus.....	7	
Phthisis pulmonalis.....	31	9
Scarlatina.....	1	
Convulsions.....	2	
Pneumonia.....	5	
Hydrocephalus.....	5	1
Peritonitis.....	4	
Enteritis.....	2	
Ascites.....	4	1
Marasmus.....	4	
Diarrhoea.....	1	1
Epilepsy.....	3	
Whooping-cough.....	2	1
Disease of stomach.....	5	1
Internal abscess.....	1	
Arachnitis.....	4	
Disease of kidney.....	3

Peritonitis.....	1
Ascites.....	2
Apoplexy.....	1
Disease of stomach.....	1
Blue disease.....	1
Hernia.....	1
Sudden death.....	1

In both these tables it will be seen that tubercular consumption affords the largest proportion of cases in which water is found in the pericardium. Diseases of the heart stand in the next place, and, generally, affections of the chest are much more frequently accompanied with hydropericardium than those of any other cavity. The largest quantity was three pints, and was the consequence of inflammation of the membrane.

The colour of the effused fluid much varied; in most instances being nearly a clear serum, in others being of a chocolate colour. This is in unison with the experience of Kreysig.

Notwithstanding the number of these dissections, they have afforded very little information as to the diagnosis of hydropericardium; nor, if we look at the tables, can we be much surprised at this result. In no single instance did the presence of fluid constitute the only disease when it exceeded a few ounces, and in those cases in which a few drachms only were found, no symptoms existed during life by which attention was attracted to the condition of the pericardium.

Having made these preliminary remarks, we may proceed to state that no very well authenticated case of idiopathic hydropericardium has yet been related. The only instance with which we are acquainted, that is on record, is one mentioned by Morgagni upon the authority of Valsalva; and even of this some doubt may be entertained. The symptoms were

dyspnoea increasing to orthopnoea, cough, mucous expectoration, and fever; and the case proved fatal. The pericardium was distended with water. But as the affections of the mucous membranes were scarcely distinguished in the time of Valsalva, and as many of the symptoms above enumerated were, if not peculiar to, at least such as are usually attendant upon bronchitis, we may be pardoned if we refer the presence of water in the pericardium to the existence of bronchitis. Nor is another case, related by Morgagni, and referred to by Kreysig, Testa, and others, much more illustrative of idiopathic hydropericardium independent of other disease. This case occurred in a nun in whom the over activity of her physician had produced hypercatarsis, and a series of anomalous symptoms for full a year, soon after which she died. The case, nevertheless, is worthy of notice in connection with this subject, although we can scarcely refer to it as a means of diagnosis.

The patient the day after the purging above alluded to became suddenly very faint upon attempting to rise from her bed, and this faintness recurred whenever she attempted to speak or move much. These symptoms continued with little variation for a considerable time; her countenance still remained healthy, and her sleep undisturbed. The bowels acted regularly, and the catamenia were as usual. Respiration in every position was uneasy. Her pulse was regular. There was no palpitation, and no pain in the chest, nor cough. The only complaint was a sense of weight in the region of the heart, and excessive nervousness. Towards the termination of her life she had sharp pains in the region of the heart; her strength gradually diminished, and at length she died. On dissection the only morbid appearances were the effusion of about nine ounces of water in the pericardium, and ulceration of this membrane. The ulceration Morgagni refers to the acrid nature of the water: modern pathologists would, probably, rather refer the whole appearances to inflammation originally, which had produced equally ulceration and effusion, both common terminations of inflammatory action.

These are the only cases with which we are acquainted, where even a pretence can exist for considering hydropericardium as idiopathic: nor does any author of late years ever regard it in this light. Nevertheless, while the science of medicine remains in its present imperfect state, every effort to forward our knowledge of the diagnosis of disease is worthy of encouragement; for if disease is to be treated successfully, excepting by accident, it must be by an accurate acquaintance with all its phenomena.

Like every other form of dropsy, hydropericardium may be the consequence of some affection of the membrane in which it is seated, or of some organic disease of other parts. In the former case it seems always to result from inflammation of the pericardium; in the latter it may be connected with inflammation, or the

simple sequence of the pericardium participating in the atonic state of the general system. Kreysig has attempted to lay down the signs by which we may distinguish effusion in the pericardium succeeding inflammation of the membrane.

According to this author, when the more prominent symptoms of pericarditis subside, a feverish state with slight exacerbations still remains, and for some time a more marked symptom is present. These exacerbations gradually increase both in severity and frequency, and are soon accompanied by anxiety and great sense of oppression. The patient is unable to lie down, and usually sits with the head and chest leaning forwards. The pulse becomes habitually irregular, the appetite uncertain, and the sleep bad. During the exacerbations all these symptoms are worse; the anxiety and restlessness become excessive, and delirium or most painful irritability, one or both ensue. This state continues for some hours, and then nearly disappears, again, however, to return after a short interval of rest. The disease lasts from seven to fourteen, or even twenty-one days. During the last few days of life the patient is less complaining, and endures positions which had previously been intolerable. A species of drunken sleep is manifested; the patient lies as it were in a dream; the action of the heart becomes weak and more irregular; the extremities are cold; the surface of the body is covered with a clammy perspiration; and death at length ensues, as the consequence of a weakened and obstructed circulation.

Such is the account given by Kreysig of this affection; but in it we see nothing to distinguish hydropericardium from hydrothorax. Many of the symptoms are common to this with other diseases of the heart and thoracic organs; none of them are so peculiar-as to mark without error the occurrence of effusion in the pericardium. Still the whole relation is excellent; and could we see the symptoms as well developed in every case, it would certainly much facilitate our diagnosis in this difficult disease. Unfortunately, however, this is seldom the case; sometimes one, sometimes another symptom is absent, and sometimes the dropsy of the pericardium is complicated with other diseases, which leave us doubtful to which affection particular symptoms are to be referred. It is at present scarcely possible to afford any certain signs by which an accurate diagnosis may be obtained.

We might here also notice the affection which Testa has named hydropericarditis of child-bed; it is, however, as in truth is the disease above described by Kreysig, a true pericarditis terminating in effusion.

Hydropericardium from organic disease.—The signs by which hydropericardium may be distinguished when complicated with organic disease, especially if this disease be seated in the heart, are even, if possible, more obscure than when simply the result of pericarditis. Corvisart, who must still be regarded as the

best author on this subject, has enumerated many signs by which the presence of effusion in the pericardium is indicated; yet a very cursory perusal will show us that they are deserving of little confidence. Patients, he observes, who suffer from hydropericardium have usually livid countenance, and black and livid lips; they experience great anxiety and oppression in the region of the heart; dyspnoea is so great as to threaten suffocation, especially when the patient assumes the horizontal position. In applying the hand to the heart, its action is found to be obscure and tumultuous, and the organ appears to beat through a soft body, or rather through a liquid placed between it and the walls of the thorax. Percussion produces a dull sound over a space commensurate with the extent of the effusion; and in some instances the left side over the region of the heart is more vaulted and elevated than the right. When the disease is of long duration, the strength fails, oedema of the extremities ensues, and, more rarely, a slight puffing over the anterior and left side of the chest.

Vieussens has mentioned oedema of the face and a dark leaden colour round the eye-lids, as more peculiarly indicating hydropericardium, but Testa justly regards these appearances as by no means peculiar to this affection. We have ourselves, in a former article, remarked that all dropsies which depend upon diseases of the chest for their origin, are usually indicated by oedema of the face; and hence it must be insufficient to mark this form of dropsy alone. On the other hand, Testa remarks, and the remark is worthy of notice, that hydropericardium very rarely exists without oedema of some part of the face; and that this oedema does not disappear before death, as does the oedema of the extremities.

Morgagni, Kreysig, and Testa have discussed at considerable length the value of individual symptoms; and they have all come to the same conclusion, viz. that they are all useless to distinguish hydropericardium from hydrothorax, and often from diseases in which no effusion is present. It would take up more space than ought to be allowed to this article, were we to go over the ground which they have trodden with so much ability; nor, considering that they at last arrive only at a negative conclusion, would any advantage be derived from such a discussion. Modern ingenuity has, however, introduced a new means of diagnosis, as well as revived and improved an old one. These are percussion and stethoscopic auscultation. With regard to the value of the first, no dependence can be placed upon it in this disease. It will indeed inform us, and that with tolerable accuracy, of the extent which the heart and pericardium occupy together when there has been no condensation of the lungs nor any material alteration in the change of parts; but should either of these occur, it would be useless even so far as we have indicated. But again, should no impediment arise from the source now referred to, percussion would do no more than intimate differences of

sound without informing us of the causes of such differences; whether, for instance, depending upon enlargement of the heart or effusion into the pericardium. Of this difficulty Corvisart himself was well aware.

The stethoscope may perhaps, in very practised hands, afford some information; and Dr. Hope thinks even eight ounces of fluid in the pericardium might be detected; "the sensation communicated to the hand and the stethoscope being that of an impulse transmitted through a fluid, and not of an organ striking the ribs immediately." We confess that we are not so sanguine in this respect as Dr. Hope; and we are much inclined to think, with Laennec, that less than a pint will scarcely afford any signs cognizable by auscultation.

The mistake made by Desault in tapping the pericardium may seem to corroborate our doubts. This distinguished surgeon made an opening into the chest between the sixth and seventh ribs of the left side near to the apex of the heart. He introduced his fingers into the chest, and perceived a cavity full of water, which he took for the pericardium. Dubois, Sue, and Dumangin, who were with him, examined the parts, and were of the same opinion; and Dessault then enlarging the opening, let nearly a pint of fluid escape. The fluid being discharged, he again introduced his finger into the aperture, and perceived a pointed conical body to strike the finger. The man, however, died in a few days; and the conical body was discovered to be the heart enveloped in the pericardium, which closely adhered to it; and the opening had been made into a cavity formed by a membrane which united the edge of the left lung to the pericardium. Here, then, the union of the pericardium to the heart, and the proximity of the fluid, would probably have obscured even this sensation of the heart beating through a fluid.

There is only one other sign which we feel called upon to consider, and this was proposed by Corvisart; but the suggestion has not been confirmed by any other author. Even this, however, is only applicable to very large collections of water. Corvisart had observed the phenomena now referred to in two instances. To employ his own words, "the beating of the heart is perceived sometimes to the right, sometimes to the left, or, to speak more clearly, in different parts of an extensive circle. Now this could not occur if the heart should be retained, as is natural, by the pericardium, whose cavity, proportioned to the volume of the organ, fixes the extent and direction of its motions. The pericardium must, therefore, be dilated, and this may happen in two ways; by augmentation in the volume of the heart itself, in which case, though the impulse of the heart might be stronger, and occupy a larger space, still it would strike against the same place; or by an accumulation of fluid in the pericardium, and then the heart, not being likewise dilated, would swim, as it were, freely into the fluid, and strike against different parts of the chest."

There can be no doubt that this is a very important observation; but Corvisart himself had only seen two cases in which it occurred: in one there were four pints of fluid, and in the other one pint. We have ourselves in vain endeavoured to detect the phenomenon, but have never yet been able; nor can this excite surprise, when it is remembered how large a quantity of fluid is probably necessary for its exhibition.

Morbid appearances.—These are seldom peculiar to hydropericardium; the essential circumstance of the disease being merely the presence of fluid in the pericardium. This fluid, we have already stated, varies much in colour; and the membrane itself sometimes exhibits traces of inflammation, increased vascularity, depositions of coagulable lymph, supuration, and ulceration. A more detailed account of the morbid appearances will properly fall under those diseases of which effusion is the consequence.

Treatment.—Of this we have very little to say in addition to what has been stated under the general head of Dropsy. Hydropericardium is so rarely, perhaps never, a solitary affection, that it cannot be treated upon any exclusive principles. Only one remedy may be proposed which it seems to us necessary to mention, and this is tapping the pericardium. This operation has been very rarely performed on the living subject; nor can we suppose it probable that it will again be proposed till experiment upon animals, and observations of injuries in the human subject, tending to prove that the membrane in question may be wounded with impunity, shall have afforded more justification for such an operation than at present exists. Certainly, however, we have no reason to believe that perfect adhesion of the pericardium is inconsistent with considerable enjoyment of life, although probably not with perfect health.

(John Darwall.)

HYDROPHOBIA.—When it becomes our duty to illustrate the nature and history of a disease, our thoughts instinctively turn themselves to the mass of obscurity which hangs over so great a majority of morbid affections; an obscurity which, under every advancement of science, diminishes but slowly, and which keeps almost all those maladies which were unintelligible two thousand years ago unintelligible still. Sometimes it may be doubted whether the disease is truly an original mischief, or merely the symptom of some other primitive disorder; whether it is not frequently confounded with affections happening to coincide with it only in a few occasional symptoms, or is not daily viewed in the most erroneous light with regard to its pathology and causes; or, in fine, whether proper evidence be not still wanting in these various respects, to enable physicians to establish any conclusion upon a firm and rational foundation. But whatever may have formerly been the case, it is no very common occurrence, at the present day, to have the doubts and hesitation of the writer upon

what may be called a disease of extreme notoriety extended to its very existence: such, however, literally happens with *hydrophobia*, of which many intelligent persons of different ages and countries have utterly denied the existence, except as a phrenitic or maniacal affection deriving its sole origin from the imagination of the patient,* or the injudicious treatment of his attendants. It seems necessary, therefore, on the threshold, to lay before the reader the grounds of our belief in the real existence of hydrophobia, reserving for future detail any other confirmatory circumstances which may present themselves as we proceed. Having briefly stated the general arguments, we shall be at liberty to carry him along with us to the history and treatment of the malady.

Our first argument is, simply, that numerous persons become affected with the disease, which is essentially characterized by *spasmodic contractions of the pharynx, and a difficulty of drinking*, (the latter generally believed to be a consequence of that spasm,) very soon after having been bitten by an animal labouring under a similar affection; and that these persons *invariably* go on from bad to worse, and finally die before the sixth day; their bodies upon dissection presenting appearances as uniform as can be expected from the great mechanical irritation produced on the adjacent secreting and circulating organs by the violent convulsions. On the other hand, we rarely observe the same train of symptoms preceded by any other cause. Now, of these victims some are mere infants, and cannot therefore be suffering under any mental impression; others are idiotical, others delirious; in neither of which states are the sources of mental terror long kept steadily in view. But in point of fact, a very large majority of hydrophobic patients, whose cases have been distinctly described in our medical records, are positively stated to have retained an adequate clearness of intellect till long after the terrible spasm and dread of fluids had established themselves, and in very many till the last moment of existence. Not a few of them have happened to be sensible, well-educated persons, of particularly strong minds. And seeing that we have for these facts the moral evidence of the entire faculty, of all ages and countries,—to assert in defiance of it that every hydrophobic patient is the victim of his own insane fears, does really seem to us to be begging the very question or proposition which those who make this assertion are bound to prove, although in direct contradiction to all medical testimony. Besides, if the cause consisted solely in a deep impression of fear, why should the disease, its presumed effect, intermit so frequently and in so many instances, as it is known to do? It cannot be said, therefore, that the proximate succession of the disease to the bite is the effect of mental emotion; and it will be easy to show that in most cases of this special class, not one of the other presumed

* C. Aurel. Lib. iii. c. xiii. p. 223.—White on Hydrophobia.

causes of hydrophobia spontanea, or rather non-rabida, were present. Consequently there is at least one form of hydrophobia of which the only constant known antecedent is the bite of a rabid animal; and this, therefore, in the present state of our knowledge, we are compelled to consider as the cause till another is shown. Secondly, the wound inflicted is not unfrequently found to hold a manifest relation to the characteristic symptoms. At first, these do not shew themselves, and the wound heals up kindly; but just before the time when the characteristic symptoms are about to appear, the cicatrix occupying the place of the wound often undergoes the remarkable alteration which we shall here for convenience technically name *recrudescence*. It swells, becomes red, livid, and painful, and the pain sometimes seems to shoot along the soft parts to a considerable distance from its origin. In other cases the wound opens of itself, and discharges a peculiar matter. Something similar is known to take place in traumatic tetanus; and although in this affection, as well as in hydrophobia, we cannot explain why the phenomenon of recrudescence does not occur in many fatal examples, yet we ought not therefore to deny that in those cases in which it does appear, the connexion between the recrudescence and the disease is most remarkable. Neither is it difficult to understand that, although the bite may, yet the recrudescence may not be essentially necessary to the appearance of hydrophobia; and hence we have full warrant to infer that the wound is the antecedent principally and determinately connected with the disease as an effect. Again, it is abundantly established by observation and experiment, that the bite of a dog produces, in animals of different species, a disease to all appearance hydrophobic; and on the other hand some experiments of M. Majendie, M. Breschet, and Mr. Earle, have led to the inference that the bite, or at least the saliva of man, may produce similar effects on the lower animals. These analogies are so forcible, that notwithstanding all the original differences between the economy of the human body and that of the lower orders of creation, we cannot refuse here to admit its application as an evidence, that upon man also the bite of a rabid dog will probably produce similar effects. Lastly, the universal persuasion and testimony of the people of every country in the world for more than two thousand years, affirming the connexion between the bite of mad dogs, and precisely the same characteristic phenomena of spasm in the throat and fear of drinking, is not to be passed over as a trivial or superstitious evidence of the reality of hydrophobia in man. It is not trivial, for the impression is deep; and a dread of pestilence is not more strongly implanted in the minds of men than the fear of hydrophobia: it is not superstitious, for it will be shown in what follows, that mankind came to a knowledge of this direful malady in the enlightened period between the days of Aristotle and the foundation of the great medical school of Alexandria; after Democritus and Hippocrates had long

freed the science from all connexion with superstition; and when the cities of Greece, Asia, Sicily, and Egypt, abounded with medical schools, and with professors alike distinguished by their cultivation of the healing art and their improvement of general philosophy. A coincidence of belief so universal cannot fairly be ascribed to accident, and is no more to be neutralized by the possible circumstance that *other causes* also may produce these symptoms, than the operation of marshy miasm in producing ague, from a well-known fact that other causes may also induce that disease, or reproduce it in the system after it has been to all appearance subdued for many years. It is still more illogical to infer, with some authors, that because the bite of a mad dog is not always followed by hydrophobia, it is therefore never succeeded by it. No known cause of disease whatever, not even the exhalations of the pest-house, the inoculation of variola, or the contact of scabies, produces its effect upon *every* person to whom it is daily applied; many escape, and probably, as in the case of small-pox, after vaccination, from previous changes in the system, which have rendered the body no longer susceptible of its influence. At all events, if we were to admit the conclusion drawn by late authors, we should be obliged to deny the influence of every exciting cause of disease, of which every successive effect, from the point to which it was first applied, to the parts ultimately involved in the affection, could not be fully traced.

Having premised these considerations, we hope we may now crave the attention of the most sceptical of our readers, while we examine in detail the principal circumstances which have come to the knowledge of the profession respecting this terrible affection.

The term *hydrophobia*, from ὕδωρ, *water*, and φόβος, *fear*, has been obviously compounded to express the principal symptom of the present disease, namely "a dread of swallowing water;" the latter fluid being taken by synecdoche as the most common liquid known then, in order to signify all other drinks as well as water. On a similar principle, the most characteristic symptom, namely the dread of swallowing liquids, or hydrophobia, seems to have been insensibly assumed as a name for the whole diversified series of phenomena which constitute the disease resulting from the bite of rabid animals. While ignorant of the proximate cause, physicians are content with naming diseases after one or more of their principal symptoms; and these denominations suffice for all the purposes of nomenclature, if they are so far prominent and uniform as readily to recal to the mind the thing signified. No medical man, we believe, ever heard the term hydrophobia, since its first reception as a word, without thinking of the disease produced by the bite of animals in the rabid state; and hence, though it may be our duty to put on record some of the more remarkable synonyms, we must say that we think very lightly of all the attempts which have been made since the days of Polybus to exchange it for one that may seem more expressive. Few

rational physicians expect to find the history of a disease condensed into a sort of essence in its name; and it ought not to be forgotten that the most comprehensive appellation is not always that which produces the most rapid suggestion—the principal end, we presume, of all individual nomenclature. Nevertheless, several distinguished French authors, of late years, have seemed obstinately bent upon some innovation; and we find, for example, in the excellent *Dictionnaire des Sciences Médicales*, and the still more recent *Dictionnaire de Médecine*, two standard works, the term hydrophobia appropriated to all cases exhibiting a dread of swallowing fluids, but *not* connected with the bite of a rabid animal; to designate, in short, every form of what is in Britain named simple hydrophobia. On the other hand, to the disease resulting from the contact of rabid animals, *rabies canina*, *rabies*, or *rage*, is in these works exclusively applied. Both terms are employed in a sense entirely conventional; for the dread of swallowing fluids, or hydrophobia, in the literal sense, is present almost alike in the simple and rabid forms of the disease; and it seems ridiculous to apply the epithet of *rabies canina* to a disease which has been produced by the bite of a wolf or a cat: and the term *rabies*, whether separate or joined with *canina*, involves the incurable fault of signifying furious delirium, a state of mind which is scarcely ever present in the disease. The ancients did not by any means fall short of the moderns in this curious research after an expressive appellation. Cælius Aurelianus allows the investigation a due share of his excellent chapter on hydrophobia; and so many authors have since adorned the pursuit with separate dissertations, that a fanciful person might almost imagine that in the name, as in the virus of hydrophobia there lurks something contagious. The ancient Greeks seem to have had a specific term for the madness of dogs, namely, *λύσσα* or *λύττα*, and we see it so employed by Homer, *Iliad* ix. 239. From this they formed a verb *λυσσάω* or *λυττάω*, and the adjectives *λυσσητὴρ*, *λυσσῶδης*, *rabidus*, *rabiosus*; terms which Homer makes his chiefs apply to Hector, while bearing all before him in the field of battle, and consequently presenting no bad image of that indiscriminate rage and effort at destruction generally displayed by the dog in a state of madness. The participle *λύττων* is likewise made use of by Plato in his *Republic*, to characterize a prince of ungovernable fury. Hence the term *κυνίλυσσα*, *canis rabies*, or *dog-madness*, has been repeatedly employed to designate this affection of the canine race; and it has been extended to the hydrophobia of man by Andreas and others. This, however, is still more extreme; for the translation of *κυνίλυσσα* is *dog-dog-madness*! an absurd pleonism, there being no *lyssa* except that of dogs. The very argument urged against the term hydrophobia, that dogs drink during their whole disease, ought to have taught writers that the disease of the dog is not the same as the disease he excites in man; and consequently that neither *lyssa* nor *cynolyssa*, nor

any other term which properly marks the disease of the dog, can rightly be applied to that of the human species. From the patient being unable to swallow any kind of moisture, some of the Greeks named it *hygrophobia* in preference to hydrophobia. Others gave it the appellation *phobodipsia*, to express the presence of thirst generally accompanying the dread of swallowing, or the dread of liquids themselves. By Polybus it is named *pneugydros*, because those affected are observed to shun or fly from water: Aurelianus translated this by the term *aquifuga*, in which, for obvious reasons, he has been little imitated. From two ambiguous passages in Hippocrates, hydrophobias have been called *brachypotæ*, i. e. *parvibubuli*, and the disease *brachypnosia*: but the word *βραχυς*, *short*, may also be applied to the intervals, and thus express in *brachypnosia* two very opposite things, either the act of drinking little, or of frequent drinking at *short* intervals. It is simply named *canis rabidi morsus* by Africanus and Avicenna. Mead proposed to name it *δυσκἀταποσια*, or difficulty of swallowing drink; and Rush, full of its relations to fever, will have it called the “hydrophobic state of malignant fever.” Quite recently, Dr. Good has attempted to restore the primitive Hellenic term *lyssa*, by inscribing the disease *entasia lyssa*.

Notwithstanding this profuse luxuriance of nomenclature, the term hydrophobia has always been and still is that by which this affection is distinguished by the rest of mankind, as well as by the best medical authors. It is the name employed by Celsus, Aurelianus, Galen, Boerhaave, Sauvages, Dessault, Linnæus, Vogel, Sagar, Cullen, and Pinel; and is still the only denomination by which the disease is known in the common language of the inhabitants of France and England, and under forms more or less translated amongst all the nations which inhabit Europe. Nor does there appear to us the least reason why it should be changed, since, as has been shewn above, it accurately answers in all the circumstances necessary to a simple name, and involves no theory with regard to the exciting cause or the intimate nature of the disease, but on the contrary seems a sort of etymological reduction of its essential character to the simplest terms; hence we venture to pronounce, that in defiance of all the efforts of ingenious men to the contrary, it never will be changed. Had it contained any intrinsic misrepresentation, any inherent source of fallacy, we should not have deemed the highest antiquity a sufficient reason for discussing its merits, far less for retaining it in a work of this description. But as it cannot be accused of either, and the reader was not to be left without some knowledge of its multiplied synonymes, we have endeavoured to bring them before him in as brief a manner as perspicuity would allow.

The nosological relations of hydrophobia appear scarcely less to have perplexed medical writers than those of its nomenclature. Concerning two radical facts all seem to be agreed;

namely, that there is one form of hydrophobia shortly succeeding to the bite of a rabid animal, and which is to be distinguished nosologically from all others; and secondly, that there are several slight evanescent forms of the hydrophobic spasm, which appear distinctly as mere incidental symptoms of hysteria and other common diseases, and are accompanied with little danger, and which, therefore, ought not to be classed as constituting any species or variety of the genus *hydrophobia*. But between these two extremes there occur an immense number of intermediate instances, resting upon testimony respecting which no rational doubt can be entertained; whose origin can be traced neither to injury from a rabid animal, nor to any previous disease existing in the system. For the moment, these may be divided into four different sections; first, those cases which arise almost immediately after the application of some obvious exciting cause, such as the bite of an animal not rabid, of the patient himself, a wound, or the influence of fear; secondly, those which are preceded by an obvious exciting cause, but between which and the appearance of the disease a considerable time intervenes; thirdly, those cases which appear to originate without any probable exciting cause having preceded; and fourthly, the numerous examples of hydrophobia which occur indeed after the bite of a rabid animal, but at an interval much beyond the period at which this peculiar injury is believed by the generality of physicians to be no longer capable of manifesting its powers. It is in the due allotment of these various candidates for nosological distribution that the difficulty of effecting a systematic arrangement of hydrophobia is mainly placed. It is not easy to invent a specific name which shall comprehend the whole or even the majority of them; for if, with M. Sauvages, we comprise them under the term *hydrophobia spontanea*, it is unanswerably replied, do you call the diseases of the first and second section spontaneous when their causes are obvious and acknowledged? nay, it is for you to prove that hydrophobia is ever generated spontaneously, since it is denied by the ablest authors. Again, if with Cullen we employ the term *simplex* to signify this series of complaints, we are instantly told there is no reason to believe that these are of a more simple nature, or involve fewer symptoms than the cases proceeding directly from the bite of a hydrophobic animal; and that if we make use of the word *simplex* merely in contra-distinction to the term *rabiosa*, such an application of it is entirely conventional. Nevertheless, as the terms *hydrophobia rabiosa* and *hydrophobia simplex* are very easily understood and contrasted with each other, especially since the latter term implies that the *hydrophobia rabiosa* is complicated (according to general belief) with the action of a poisonous virus, they are in common use in this country, and may occasionally be employed in the present article. As, however, all that seems wanted for the second species of hydrophobic affections is

such an epithet as decides that the cases arranged under it do not originate from the bite of a rabid animal, (the multiplicity of causes, and our total inability to trace these causes to their obvious effects, rendering every other appellation more or less exceptionable,) we humbly conceive that some such specific terms as the following would obviate every objection.

Genus Hydrophobia.—Great restlessness and hurry of mind; horror of and difficulty of drinking fluids, accompanied by clonic spasm of the pharynx, and spasmodic constriction of the muscles of the chest.

Species 1.—*Hydrophobia Lyssodes*, succeeding, within the period of two years, to the bite of an animal supposed to be rabid.

Species 2.—*Hydrophobia Paralyssodes*, not preceded, within the period of two years, by the bite of a rabid animal, or by any other than anomalous causes.

We shall thus reconcile popular nomenclature with the admirers of Dr. Good and of the language of Homer, avoid all verbal criticism, and enable future reasoners to arrange the different modifications which the disease assumes as *varieties* under their respective species; while the symptomatic imitations of the disease may be disposed as synonymes under an anomalous species of *hydrophobia symptomatica*, as has already been done by several eminent authors. In this manner we have—

Hydrophobia Lyssodes.—Varieties, *canina, felina, avicularis? insectorum? fomitus? saliva?*

Hydrophobia Paralyssodes.—Varieties, *traumatica, inflammatoria, phrenitica, meticulosa, nervosa, pathetica, febrilis*.

The symptomatic species are, *hysterica, febrilis, hypochondriaca, maniaca, melancholica, cynanchica, venenata*.

Let not our readers imagine that the reflection we have bestowed upon this arrangement is barren of all useful application. On the contrary, nothing is so common, on the narration of a new case, as to hear it asked,—But is it certain that the case is one of genuine hydrophobia? Were the pathognomonic symptoms present? Was it not rather one of those fatal spasmodic affections of the throat in the production of which animal virus has no share? And a person unacquainted with nosological arrangement often finds it difficult to answer such queries, as he must necessarily waver both with regard to the date at which the poison may still work its effects, and the circumstances which connect the approach of the animal with the ultimate symptoms, if he do not even hesitate much about the symptoms themselves. From the usual neglect of such an arrangement may fairly be traced that scepticism regarding hydrophobia which we so often meet with among members of the profession sufficiently sensible and unprejudiced, but whose attention has been otherwise directed. It appears unnecessary to dilate upon the criticisms which have been made by authors upon the group of symptoms

which have been assumed by various nosologists, as constituting the character of the disease. Nothing was more natural than that the fears of mankind regarding the communication of this formidable affection,—fears which may be traced to the time of Aristotle,—should clothe it in all the terrors suggested by an apprehension so justly vindicated by what they observed to take place in other animals. Posterity has added very little in this respect to the horrible train of suffering already so graphically described in the pages of Aurelianus; and if some of them, since exploded by the critical science of our own day, were believed in and quoted as characteristic by the nosologists who have preceded us, these writers seem hardly to be chargeable, in fairness, with more blame than the misfortune of having lived before these errors were discovered. They are not answerable for their age; and excluding these faults, enough still remains in their definitions to enable us to recognise the disease they describe; and if there did not, it would still be very poor logic to infer that, because their definitions had failed, the disease was indefinable or did not exist. The hydrophobia of Cullen was the same as that of which we treat, although he erroneously believed it to be characterised by a desire to bite and a loathing of liquids. In the last place, it was equally illogical to consider the occasional absence of some one of the characteristic symptoms a sufficient reason for withholding the general name of hydrophobia from the disease, and yet this has been a great stumbling-block with some of our most ingenious writers. Such reasoning is correct only in abstract mathematics and abstract logical discussion, where the things defined, being pure entities of imagination, can suffer no gradation without demanding a corresponding change of terms. But in nature, and more especially in organic beings, every thing is gradation and change; and no genus of plants or animals, and still less of diseases, could be subdivided into its species and varieties which do actually exist in nature, were this rule to be rigidly observed. No disease, for example, can be better defined by nosologists than pneumonia; yet how often do the physicians of the present day, by the aid of the stethoscope, proximate auscultation, and other well-known forms of minute observation, discover latent modifications of it in every degree of advancement, which but a few years ago would only have come to their knowledge long after by the appearance of adhesions which they might accidentally observe on dissection. Instances might be multiplied to almost any number; but it will be more practically useful to observe that a new case of disease is to be classed by the physician rather according to its general coincidence with the symptoms of some well-known type or form, than according to the presence or absence of some individual symptom; a circumstance which, in the varied irritability of the whole system or of single organs, is often quite fortuitous: and the writer who should deny that the fatal disease suc-

ceeding to the bite of a mad cat, for example, is not hydrophobia because it is accompanied with scarcely any dread of water, although it agrees in all other indications, may seem to reason with the metaphysical accuracy and the scrupulous definition which distinguish a geometer, but we should distrust his knowledge of the principles of physic, a science which requires great allowance to be made for incidental variations.

From the earliest antiquity of which we have any record, the dog has been the companion of man. In the book of Exodus cattle torn by wild beasts are ordered not to be eaten, but to be given to the "dogs,"—an expression which proves that these animals were already the constant attendants of man, and assisted in his pastoral labours. It was no doubt the impurity of their food that has rendered their name synonymous with every thing that is impure or vile throughout the whole of the scriptures. Still there is no allusion made to hydrophobic disease any where in the sacred volume, a circumstance which is perhaps best explained by the fact that, even down to the present day, canine madness is unknown in Syria and Egypt. We have already said that the disease was well known to Homer, and applied by him, with his usual critical exactness of similitude, to the indiscriminate havoc with which Hector sweeps through the battle-field of his enemies. Thus,—

—————"Ἐκτωρ δὲ μέγα σθίνει βλαμεινῶν
Μαίνεται ἐκπάρῳας, πίνουσ' αἰ, οὐδέ τι τίει
Ἄνείρας, οὐδέ θεούς· κρατερὴ δὲ ἔλυσσα δίδουκεν.

Iliad ix. 237.

Τούτῳ δ' οὐ δύναμαι βαλῆειν νύνα λυσσητῆρα.

Iliad viii. 299.

—————ὁ λυσσώδης, φλογὶ εἰκελος, ἡγεμονεύει
Ἐκτωρ.

Iliad xiii. 53.

The poet, with much propriety, puts these words into the mouth of Ajax his enemy, for *dog* was already a term of reproach among the Greeks* as well as the Jews. He no where mentions the disease as actually existing in man. In the writings of Hippocrates, there occur at least two passages, the singular language of which makes it not improbable that the physician of Cos had seen hydrophobia, and was then speaking of its symptoms, but that he did not recognise it as a separate disease, and merely considered it as a variety of phrenitis or mania, affections with which it has always been but too easily confounded:—Οἱ φρενιτικοὶ βραχυπῶται, ἴφου καθαπτόμενοι, τρομώδεις. Prædict. lib. i. p. 69. Οἱ φρενιτικοὶ βραχυπῶται, ἴφου καθαπτόμενοι, τρομώδεις ἢ σπασμώδεις. Prenot. sect. ii. p. 131. We transcribe the passages, but are unwilling to strain them so far as Aurelianus and others have done; indeed, no indisputable mention of the disease occurs any where in his works, either in the genuine or the sus-

* Iliad. i. 225.

pected. There is almost certain evidence, however, that the disease was well known to his friend and contemporary Democritus; for we are told by Cælius Aurelianus, that, in his book upon *Opisthotonos*, Democritus distinctly treats both of the hydrophobic disease in man, and its origin from the bite of a rabid animal, and that he seemed to consider it as a variety of tetanus, an opinion which has been embraced by many of the moderns:—"For Democritus, who was contemporary with Hippocrates, not only makes mention of this affection, but even describes its cause when speaking of *opisthotonos*."* And in another place, speaking of the cause of hydrophobia, "Indeed Democritus, whilst treating of *emprosthotonos*, ascribes the seat of the disease to the nerves;"† by which in his time were chiefly meant the tendons, ligaments, and other white tissues. Now we learn from several passages in Gellius, the contemporary of this well informed author, that the works of Democritus were still extant in his time, and of frequent reference and high estimation; and it seems most improbable that Aurelianus would have referred to the chapters in which the passages were sure to be sought for, if he had wished to misquote, or to mislead the disputants in a controversy which, he informs us, was then become hackneyed, and the merits of which he appears to consider with perfect coolness. Democritus, be it remembered, was a great traveller, and may have become acquainted with the communication of hydrophobia to man in countries situated beyond that sphere of information to which the industry of the great father of medicine had ever extended. At all events his opinion made little impression on the Greeks; for we find Aristotle, nearly a century afterward, asserting that the hydrophobia may be communicated from one animal to another, but not to man. "Dogs," he affirms, "are subject to madness, cynanche, and a sort of gout or lameness. The first of these diseases renders them rabid or furious, and all the animals which they bite become equally affected with madness, with the exception of man. The malady occasions the death of the dogs affected, and of every animal that is bitten by another animal, still excepting man."‡ This repeated negation of the actual existence of human hydrophobia would scarcely have been made by so grave a writer as the Stagyræite, unless he had heard the contrary asserted under some degree of authority; nor could he have safely committed it to writing, unless he had previously contemplated the different circumstances. Indeed Professor Sprengel seems to think that Euripides, who was prior even to Democritus, alludes to it in the *Bacchæ*, v. 337. "Acteon

..... mourut de l'hydrophobie.* C'est la plus ancienne trace que nous trouvons de cette cruelle maladie."† Upon referring to the *Bacchæ*, however, we confess we cannot discover the most remote trace of an allusion to hydrophobia. In that part of the drama to which Sprengel refers, Cadmus is counselling Pentheus to join in the worship of Bacchus and Semele, to dread the danger of contemning the Gods, and, as an example, to take warning by the fate of Actæon. The words are—

ὄρας τὸν Ἀκταίωνος ἄθλιον μῦθον
ὃν ὠμίοντο σκύλακες, ἃς ἰδὲ φάτο,
διεσπασάντο, κρείσσον ἐν κινήσει
Ἀρτέμιδος εἶναι κομπάσαντ', ἐν ὄργῳ.

Which may be thus simply translated into English:

Thou seest the wretched fate of vain Actæon,
All torn and scattered by the raw-fed hounds
He cherished; meanwhile boasting in the chase
To excel the great Diana, forest queen.

Still the testimony of Apollodorus would be curious, if it evinced that human hydrophobia was known and believed in shortly after the time of Aristotle, and long before the age of Asclepiades; a fact which is strongly corroborated by what we have already stated from Aurelianus, of the opinions respecting hydrophobia maintained by Andreas, who flourished two hundred and four years before Christ. Apollodorus, whose words follow, lived in Egypt under Ptolemy Physcon about one hundred and thirty-three years before Christ, more than half a century before the period at which Asclepiades flourished. His work is a history of the Gods, wherein, describing the death of Actæon, he says, — οἱ πλείονες λέγουσι ὅτι τὴν Ἀρτέμιιν λουομένην εἶδε. καὶ φασὶ τὸν θεὸν παραχρῆμα αὐτοῦ τὴν μορφὴν εἰς ἔλαφον ἀλλάξαι. καὶ τοῖς ἐπομένοις αὐτῷ πεντήκοντα κυσὶν ἐμβάλλειν λύσαν, ὑφ' ὧν κατὰ ἄνθρωπον ἐβρώθη. Artemidorus, as we learn from the *Symposiaca* of Plutarch, must therefore have been mistaken, in asserting that Asclepiades the Bithynian was the first who introduced this disease to public notice. This Artemidorus, who lived down to about the time of Adrian, must not be confounded with the follower of Erasistratus, of the same name, who was a native of Sida, and who flourished, according to Sprengel, two hundred and twenty-three years before Christ, and is celebrated by Aurelianus for his doctrine respecting the seat of hydrophobia, which he placed in the stomach. In this he was partly opposed by Gaius, a follower of Herophilus, and who wrote a treatise on hydrophobia, or the "dread of water," about the same time; and who seems to have been inclined to place the seat of the disease in the nervous system, and more especially in the pneumo-gastric portion of the *par vagum*.‡ The nerves were divided by Erasistratus into nerves of sense and nerves of motion; the nerves of sense origi-

‡ "Gaius, Herophili sectator, libro quo de timore

nated from the brain itself, the nerves of motion from its membranes; and in the latter number no doubt was reckoned the eighth pair, as we see it in this passage. Asclepiades, or at least the greater number of his followers, referred the chief seat of hydrophobia to the membrane of the brain; the irritation of which, according to him, was the principal cause of all mental diseases, as phrenitis, lethargy, epilepsy.* Others of them maintained that it chiefly occupied the diaphragm, as that membrane was much affected with pain during the disease. But Artorius, the most distinguished of his followers, who afterwards became the physician and familiar friend of Augustus, but perished at sea shortly after the battle of Actium, reverted to the doctrine of Artemidorus, and assigned to the stomach the honour of being the original seat of the disease.

We have thus been enabled, by the aid of modern research, to demonstrate to the reader, 1. that the hydrophobia of dogs has been known from the earliest ages; 2. that there is every reason to believe that human hydrophobia was considered as an established disease by Democritus and Polybus, and had been heard of by Aristotle; 3. that its nature and treatment were discussed in the school of Erasistratus by his immediate followers; 4. and lastly, that Asclepiades does not seem to have added any important observation to what was already known on the subject, though his followers rather than himself propounded some unsatisfactory conjectures as to the seat of hydrophobia. Nevertheless, the distinct account of the nature and treatment of this disease delivered by Celsus, who was an auditor of Themison, the successor of Asclepiades, at Rome, evinces rapid progress towards an accurate knowledge of this formidable affection, from the no very distant period at which it most probably became generally known to the world through the medium of the school of Alexandria. Instead of quoting a work so common, we shall merely extract the substance of what was known to this admirable eclectic. The disease named hydrophobia usually arises from the bite of a rabid dog, the wound of which has not been properly treated by preventive measures. The suffering is terrible, the patient being tormented at the same time with the dread and the desire of water; and under this he gradually sinks with very little chance of recovery. The only known remedy is to throw him unawares into a pond before he sees the water, where, if he cannot swim, he will swallow a sufficiency of water while he sinks and rises by his own efforts; but if he swims, the same end is to be attained by the assistants dipping him under water from time to time. In this way the thirst and dread of water are both made to disappear. There is

aquæ scripsit, ait cerebrum et ejus membranam pati. Etenim voluntario motu servientes nervi atque stomachum colligantes, intium vel originem inde sumpsisse noscuntur.—Aur. ib.

* *Aurelianus.*

some danger, however, lest the enfeebled patient should be carried off by cramps or convulsions from the effects of the cold water; to avoid which he is immediately to be put into warm oil. Free doses of opiates combined with aromatics and antispasmodics may be given either as antidotes or remedies; but if the disease has already supervened, they may be given in pills in preference to the fluid form. When the dog which inflicts the bite is known to be mad, the virus is to be extracted by the cupping glass. The wound is then to be cauterized, unless it happen to be in muscular or nervous parts: if the cautery cannot be permitted, bloodletting will be useful. The sore after the cautery may be dressed with the usual irritants; but if the cautery has not been employed, the wound must be treated with more active escharotics, and finally healed up. Immediately after the accident, some send the patient to the bath, where he is made to sweat freely, and lay open the wound by scarification in order that the poison may escape in greater quantity, and follow up the practice with a liberal allowance of the strongest wine, which is an antidote to all poisons.

Such was the state of knowledge with respect to this disease in the Augustan age, and Sprengel thinks it owed a considerable share of its precision to the singular circumstance of Themison, the distinguished professional teacher of Celsus, and of nearly all the medical men then living, having himself become affected with simple hydrophobia, and narrowly escaped; an event which we may be sure would be copiously alluded to in his lectures, although Aurelianus gravely asserts that he was always threatened with a fresh attack the moment he began to describe the disease. “*Ferunt,*” says Dioscorides, “*Themisonem medicum amico aquam timentem, in eandem incidisse affectionem, nec nisi post multos labores servatum.*”*

It seems almost certain that Dioscorides was contemporary with Themison, and he would not have omitted the practice of bloodletting in hydrophobia recommended by Celsus and Eudemus, had it been known to him; nor yet the ingenious expedient of endeavouring to sweat out the poison by means of the hot-bath, or the formidable auxiliary of repeated submersion in cold water. Let us give Dioscorides, however, with the vulgar, to the reign of Nero, and we shall see that terror had already begun to magnify the natural horrors of hydrophobia. “*Some patients,*” he affirms, “*bark like dogs, fly upon and bite all near them, and like the former animals communicate the disease to those unfortunate members of their own species whom they have torn.*” Like Celsus, he makes distinct mention of the poisonous virus presumed to be injected by the teeth of the dog, and orders it to be sucked out by the mouth or by the cupping-glass, which is to be strongly ex-

* *Lib. vi. de canis morsu, p. 733.*

hausted for this purpose. His precepts for scarification are precise as well as judicious; he insists on the excision of the bitten part, and in certain cases recommends amputation. In these severe precautions he speaks from his own experience, by which he has preserved many persons that were bitten, from the super-vention of hydrophobia, which disease, when once established, he deems quite incurable. He is the first writer now extant who declares that he had himself seen and treated the disease. The absurdities concerning hydrophobia collected by the elder Pliny only merit allusion in so far as they evince that the terror and exaggeration it produced were much greater among the vulgar than among physicians; but the perusal of the able treatise on hydrophobia which occurs in Cælius Aurelianus affords sufficient proof that with the latter also the alarm was progressive. He, or the author he has been supposed to translate, lived about the same time with Galen, in an age still very learned, about the year of Christ 200-230. Not only do his hydrophobic patients bark like dogs, and communicate the disease by biting to man, but "their voice has a barking tone, and they roll their bodies up from head to heel, in the spiral manner assumed by the dog in laying himself to rest: they walk with the level, slow movement of persons carrying water in a full vessel; the tongue projects from the mouth; the bile that is vomited is most frequently black. A moribund patient ran upon a mad dog whom chance presented, and bit him furiously, then rolled himself up like a ball and expired. To inhale the air contaminated by the breath of the rabid dog was sufficient to produce the disease," &c. Still we are not to measure the importance of Aurelianus by the scale of his errors, or, to speak more truly, by the errors of his age; his description of the phenomena of the disease is for the most part surprisingly faithful; indeed so exquisitely graphic, that to copy it here would be to anticipate much we have to say in the succeeding history of the symptoms. His notions of the prognosis and diagnosis are generally just and sagacious; and though his method of cure derives a very distinct character from the theories of his own sect, (the methodists,) yet he has added with an impartial hand the treatment recommended by others. Lastly, he has given a very instructive view of the different controversies respecting hydrophobia which prevailed in his time, and compared them with each other with an intelligent fidelity which, in spite of his barbarous Latin, is always highly interesting. No student of hydrophobia should omit to read this part of his work. Galen, his contemporary, and in some measure his predecessor, was a great collector of what had been done before him, and his opinions swayed the schools for 1300 years after his death. It may be sufficient, then, to say that the sentiments of Galen with regard to hydrophobia were those of all mankind at the revival of letters. He appears to have turned his powerful mind to

this subject with particular attention. He invented several antidotes against hydrophobia; one of which, the ashes of the river crab, he assures us he had never known to fail. He compares the operation of the canine virus to the action of slow poisons, which, though given daily, only produce a visible effect after a certain time. The virus is like wood placed near the fire, which becomes gradually hotter and hotter, and at length bursts into flame and is consumed. The virus is by no means idle in the wound, although it does not betray itself by the least symptom for many months, in one case known to himself, for a whole year. Canine virus thus proceeding step by step slowly generates a disease, which sinks deeply into the solids, and is therefore so much the more tractable, just as we see taking place in leucæ and other obstinate forms of leprosy. The dread of water he conceives to arise from mental aberration, which he calls *impaired judgment*. In addition to his antidotes, he orders the excision of the part bitten to be made of a circular form, in order that every part tainted may be removed, and the disk thus laid open is to be kept raw by escharotics for forty days. Alyssum calycinum, or madwort, is recommended for a cure; as also the liver of the mad-dog which had bitten the patient. He gives a tolerably fair account of the signs of rabies in dogs, at least in the more violent cases. He attributes the original occurrence of hydrophobia among dogs to the spontaneous corruption of their fluids; and as his theory of the origin of diseases, now better known by the name of the humoral pathology, referred almost all complaints to a similar degeneration of the humours, he finds occasion to recur frequently with triumph to this instance of the canine virus. On one occasion he gravely draws a parallel between the self-generated poison that produces hydrophobia, and the self-generated poison that, as he imagines, produces phrenitis. The reader will at once observe that the notion of spontaneous hydrophobia, so long maintained, and not yet entirely relinquished by some authors, as by M. Rochoux, is a legitimate portion of one of the most exploded doctrines of Galen, and is supported by no better evidence at present than it was in the time of its ingenious author. With the exception of some oriental flourishes, such as the presence of little dogs in the urine of hydrophobic patients, we find the Arabians copy the Greeks with great closeness. But as some of them, Avicenna for example, are more systematic and more copious than the Greeks themselves, they may still be read with advantage. Thus the last-named author notices both the peculiar apoplectic termination of hydrophobia, and the changes occasionally affecting the urinary organs; facts which scarcely occur in the Greek or Roman writers. Africanus, a learned follower of both in the darkest age of our era, has added nothing new.

We have thus come to modern times, and in these we have not been able to resolve the question at what time arose the custom of

smothering hydrophobic patients by means of beds or pillows. Of this horrid practice no trace is to be discovered before the sixteenth century; and next to the burning of witches, it affords the most pregnant example of fear, purely imaginary, becoming the cause of the most detestable public crimes. The apprehension of danger from the breath, saliva, or bite of the unfortunate sufferer, combined, it would seem, with an obscure notion of the disease being attended with something like demoniacal possession, were the original apologies for resorting to this cruel security, the consummation of which the morbidly timid patient dreaded from the approach of every person that entered his apartment or advanced to his bed. Hence the fury, the repugnance, and frequent attempts to injure the by-standers, so prominent in the histories of hydrophobia recorded during the two last centuries, and so rare in the present. Professional scepticism and critical inquiry, by shewing that these fears were entirely without foundation, have alone relieved humanity from the reproach of these delusions, and the sufferers from the unspeakable horror of being murdered on their death-beds, often by the hands of those whom of all others they most loved; for the frequent opportunities of inspection after death, afforded by the now zealously cultivated science of anatomy, has never cast any additional light on the subject.

In presenting a view of the symptoms of rabid hydrophobia, we are enabled to derive less benefit from arranging the phenomena according to the order of time than in most other diseases. The latent period is so irregular in point of duration, and affords so few marks of the presence of disease in the system, that some able physicians have felt inclined altogether to dispute its connexion with hydrophobia. The stage of recrudescence, however, observes a tolerably uniform relation towards the succeeding disease, since it generally occurs a few days before the latter is constituted; but then it is often wanting, and even when present, seems sometimes a precursor, sometimes a symptom, of the third stage. Nay, the pharyngeal spasm and dread of fluids, the nervous agitation and gastro-pneumonic symptoms, have all been described as occurring in almost every possible order of succession in different individuals. The true key to this endless diversity is found in the fact, that by far the greater number of the symptoms which fall to be recorded are of a secondary character, in consequence of which the time and intensity with which they appear are greatly regulated by the intensity and time at which the cardinal symptom they follow has showed itself. These cardinal symptoms are five in number: first, a depressed, excited, or altered state of the nervous system of the individual; second, a depressed, excited, or altered state of the mind; third, fever; fourth, difficulty of swallowing fluids; fifth, gastro-pneumonic symptoms. From one or other of these every remaining symptom is believed to flow. But as observation teaches us that any one of

these may be the first to show itself, and any other of them may follow it in succession, it is easy to discover, without resorting to the law of permutation, that the varieties in this respect presented by the cases actually recorded must be very numerous, though all coinciding in one common circumstance,—that whatever may happen to be the order in which these cardinal symptoms supervene, they never extinguish each other, or again disappear. Still, as it is the nature of the human mind to pass forwards from cause to effect, and consequently according to the progress of time, we shall adhere to established practice in this respect, and tracing the symptoms in that order in which they most generally occur, rest satisfied with having endeavoured to select the course which presented fewest faults. We divide this disease, therefore, into three periods, namely, the stage of *delitescence*, the stage of *recrudescence*, and the stage of *spasm*.

First stage, or delitescence.—In the first stage there are generally few symptoms to be observed, except such as are usually found to occur from the bite of the most healthy animals. The wound, whether dressed, or, as often happens, neglected, heals up kindly, leaving a cicatrix, which differs in no respect from that which supervenes to a similar wound inflicted by the teeth of an animal in the best health. It may be remarked that in many cases the injuries inflicted by hydrophobic animals do not involve any extensive laceration, a circumstance which may be attributed to the sickness of the animal and the unsteadiness of purpose during this malady. The younger Cuvier has observed that the great characteristic of the animal mind, as compared to that of man, appears to be the facility with which it passes into the state of rage or fury, and remains governed by its influence; but in the hydrophobic dog this instinct seems often to be modified into a snappish irritability, by which the creature is easily induced to bite, but does not inflict the wound with much energy, nor attempt to repeat it. Huntsmen, we are told by Rush, accordingly divide the rabies of dogs into the *sullen* and the *furious* hydrophobia, in which latter form the lacerations inflicted by the dog are deep, large, and frequently repeated. In another place we shall endeavour to shew the effect of education and of the original disposition of the animal in determining the frequency of the sullen and the furious forms of the disease; but for an example of extreme injury of this kind the reader is referred to Dr. Hamilton's Appendix, page 325. The man had a large wound on the throat, which laid the trachea quite bare to a considerable extent, and which likewise appeared to be considerably bruised; one on the cheek, which enlarged the mouth a full inch; a smaller one lower on the chin, and another, lower than the former one, on the throat, which evidently proved that the animal had changed his hold.

In most cases, however, pain has been felt in the cicatrix a considerable time after the accident; but such a feeling is so frequent in the seat of wounds recently healed, that its

occasional presence after the bite of mad animals ought not perhaps to be considered as any thing singular or characteristic. In several examples upon record* slight fever came on very soon after the accident, and continued till the appearance of the hydrophobia, which in such instances supervened in the course of a few days. But as in general the period of delitescence in genuine hydrophobia is seldom shorter than forty days, or longer than twenty-four months, such cases have by many writers been considered to originate purely from the fever or the mechanical irritation, and consequently referred to the non-rabid species. We may take an opportunity to remark that we have here, as well as in our definition, assumed two years as the longest period of delitescence, because it seems to be the opinion maintained by the most rational medical writers upon this subject, from Dioscorides downwards; and because Drs. J. Hunter, R. Hamilton, and S. Bardsley, have shewn that all the credible cases on record occurred before the eighteenth month; likewise because we have heard of no instance of recrudescence taking place in the wound after this period; and, finally, because, so just is the instinctive impression left by experience, that every medical man would hesitate were he to hear in the course of his practice of an individual case of hydrophobia referred to a cause much anterior to this limit. This, however, we may do, without pretending to assert that it is impossible for the cause of hydrophobia to lurk longer in the system than two years; but we say that the connexion between the bite and the spasm has not been satisfactorily traced upwards beyond this point; and that if we were to take a thousand persons who had survived the bite of a mad dog during two years, we should not at any time afterwards find one of these persons become affected with hydrophobia without the infliction of a new bite.

In the period which intervenes between the healing of the wound and the second stage, little satisfactory has been observed; a few individuals have become retired, gloomy, and melancholy, the countenance expressing considerable anxiety; but as the pulse, skin, and other indexes of the functions continue natural, it seems impossible to affirm that these signs of depression are not the sole offspring of mental anxiety regarding the hazard in which they in general know but too well their life is placed by the accident. The other symptoms attributed to this stage by authors seem purely accidental.

Second stage, or recrudescence.—The commencement of this period is deservedly one of great alarm to the patient, and accordingly it is one about which the medical man is for the most part consulted early, and the progress of which, therefore, he is furnished with a fair opportunity of observing. It may be added that, when it occurs, the patient and the practitioner have each a longer warning, and for that reason a more promising chance of obtaining a

cure of the hydrophobia which generally follows; although some have said that the recrudescence itself is an indication merely of the greater activity of the virus and the more exasperated form under which the malady is about to appear. At first a pain is perceived in the cicatrix, at times attended with itching, but in general resembling the aching of rheumatism, which in some cases shoots to some distance along the limb affected, and in others degenerates into a species of torpor in the part itself. In one case under our own care the sensation of the thumb bitten was that of torpor, and such extreme rigidity that its joint could not be bent: meanwhile the sensation of pain was in the neck and shoulder. The thumb was without redness or swelling. Sometimes the cicatrix is merely affected with a sense of coldness, with stiffness, extending along the limb; and in one case the arm thus affected became paralysed. In a few cases the pain does not begin precisely in the wound, but in some part near the trunk, as the shoulder or hip. The scar becomes red, swollen, sometimes livid, and in one case was surrounded by a papular eruption;* and in the course of a short time it opens and discharges a peculiar ichor. Meanwhile flying convulsive pains are felt in various parts of the body. As the disease proceeds, the patient, according to Dr. Marcet, complains of pains shooting from the wound to the region of the heart, and in general both he and Babington, with Professor Callisen, have observed in different cases that these recrudescent pains seem always to follow the course of the nerves, and do certainly never inflame or irritate the lymphatic vessels and glands in the vicinity, though passing in a parallel course towards the trunk. Thus a bite on the upper extremity produced pain of the arm and shoulder, but did not affect the axillary glands; and from a similar wound of the leg the pain was conveyed to the hip and loins, but no irritation of the saphenic systems of lymphatics, or of the glands of the ham and groin, were observed to take place. We may add to the above, the entire absence of any fact contrary to this observation in the works of the numerous authors who have written on the subject. In some cases the wound does not open, but a sense of torpor, pain, and occasionally of roughness in the integuments, shoots along the limb which has been wounded. In an instructive case of this kind related by Mr. Oldknow, of Nottingham, in the fifth volume of the *Edinburgh Journal*, though the patient was wounded in three distinct places by the same dog, namely, the scrotum, the thigh, and the left hand, yet the uneasy sensations were perceived in the arm alone, *though last bitten*; as if the hydrophobic, like tetanic action, were most easily excited by irritation of the extremities. These recrudescent symptoms took place forty-two days after the bite, and four days before the hydrophobia became confirmed. It is seldom that they occur longer than six days

* *Edin. Med. Surg. Journ.* vol. iii. p. 414.

* *Edin. Med. Surg. Journ.* 1807.

before the disease becomes marked, and the most general term of their appearance seems to be two or three days before hydrophobia supervenes. In one case which we attended, and which we have also described, the patient died on the seventh day after the pain commenced in the part bitten, and fifty-six hours after the hydrophobia had distinctly commenced. The recrudescence symptoms, therefore, occupied more than four days. With regard to this point, however, and to the relative frequency with which the symptoms of the second stage are present or absent, no very precise information can be obtained. They are rarely mentioned in the more ancient cases, and occur so frequently in those of modern date, that the difference can only be attributed to the older writers having considered the state of the cicatrix with little attention. By Aurelianus, however, and consequently by the authors whose collective views he represents, this symptom was beheld in a most important light: "Præpatitur enim ea pars, quæ morsu fuerit vexata; unde initium denique passionem (s. c. hydrophobicam) sumere, nemo negat." This, however, is not the only medical observation that seems for a time to have suffered a certain degree of oblivion. In point of fact, it has been proved by Dr. Hamilton that by far the greater number of hydrophobic cases commence between the thirtieth and fifty-ninth day after the bite, and consequently at a time when the wound produced at first by the animal, and afterwards enlarged by the surgeon, is in many cases scarcely healed up, and almost always retains that high degree of sensibility proper to recent wounds, and which generally gives rise to considerable pain upon any great change taking place in the system; often, indeed, from mere vicissitudes of the weather. In several instances the pain has been perceived immediately after a debauch, and in one remarkable example it darted into the part the moment the patient was told that another person bitten by the same dog had died of hydrophobia. Though there can be no doubt, therefore, of the actual occurrence of this recrudescence in examples taking place long after all the superinduced sensibility of the part had disappeared, or where re-opening, discharge, or eruption had taken place around it; yet it is not easy to come to a conclusion in cases where the circumstances have been different. A late distinguished nosologist, Dr. Good, has received this phenomenon of recrudescence, which without doubt is very general, into his definition of hydrophobia; and we have judged it necessary therefore to explain, as far as was attainable, the modification to which this character is frequently subjected.

Third stage, or hydrophobic phenomena.—

This assemblage of symptoms, from its fatal event, the pity, consternation, and horror excited in beholders, and its obvious diversity from all other maladies afflicting the human race, whilst the latent and recrudescence periods which succeed the application of the exciting cause differ little from any other morbid states of the system, has very generally been consi-

dered as constituting the whole generic disease of hydrophobia. In strict accuracy, however, this whole group is to be considered merely as a symptom which may be resolved into separate parts, but yet simply indicates a single stage, such as is well known to occur symptomatic of many states of disease or irritation in the system; nor is there any better reason that the patient's health is entire and the disease quiescent, during the two first periods, than in that period of calm composure, facility of drinking and swallowing, absence of pain and mental suffering, which appear so generally for some time before the sudden death of the patient, and which sometimes, as in Dr. Johnston's case, interposes itself in the midst of the disease under the form of remission. We are in no hurry to anticipate the different views that have been taken of the mode or train of action by which the bite of a rabid animal produces this horrible disease; being different, they cannot all be true, and could therefore render us little service here. But, however unknown, they exert an operation on the day in which they render the disease cognizable to the senses, which they could not put forth before, and have therefore been undergoing a series of changes themselves, or operating a series of changes in the constitution from which has resulted this increase of power. From the moment of the bite, then, a morbid action is in progress and accumulation, and he who would deny this may equally deny that the death of the patient, in many instances so visibly disjoined from the paroxysmal state, is owing to the same cause; he must deny, also, that it produces the return of this state after the remission. Yet this series of paroxysmal symptoms is that to which the attention of the practitioner is chiefly directed, and he is, therefore, very easily led to consider it as the essential part of the disease. For some days previous to that on which the disease presents itself, the countenance of the patient indicates anxiety, and he is himself conscious of a restless, rather depressed state of mind. The eyebrows are contracted, the face tumid, and there is headach with tremors. In a certain number of cases a sense of general chillness, like that preceding fever, is perceived, before any more marked symptoms appear. He is sometimes drowsy through the day, and in other instances has his sleep broken and disturbed in the night. The disagreeable feelings originating from the cicatrix go on to increase; occasional sighing, unaccountable flushes and rigors of momentary duration, and in a few cases slight febrile symptoms succeed. A sudden loathing of food has been repeatedly observed at this period, the patient being sometimes surprised at finding his usual appetite converted into aversion on sitting down to table; and in other instances he becomes suddenly affected with nausea or vomiting. In some persons the peculiar pain, usually referred to the scrobiculus cordis and diaphragm, has been first perceived at this instant, and in one or two cases appeared to originate in the violent efforts made to vomit; but the symptom gene-

rally comes on considerably later. A sense of stiffness, gradually becoming painful, is now felt in the back part of the neck, and extending forwards along the basis of the jaw towards the root of the tongue and the pomum Adami of the larynx. Sighing is more frequent; the respiration is easily hurried; and there is often some headach complained of at this period. If the patient attempt to swallow any thing, he finds himself unable to perform that office; the matters introduced are rejected with violence from the mouth, and the muscles of the mouth and pharynx are seen by the bystanders to be thrown into violent convulsions, in which not unfrequently the muscles of the face participate. This is the pharyngeal or hydrophobic spasm, which, by creating a dread of swallowing fluids, has given name to the disease; for although patients are generally able to swallow food and other solid substances with tolerable facility, yet any attempt at drinking, be the fluid what it may, is almost sure to be followed by the spasm and sense of suffocation. Though in most cases the painful spasm is the only cause of the dread of swallowing fluids, and eventually of the fluids swallowed; yet this fear may, in its turn, become the cause of the spasm, the patient, by endeavouring to avoid its recurrence, often originating the very motions which produce it. The same error of function is frequently observed to take place in these parts in persons who find a natural difficulty in swallowing pills, in painful cynanche, and in eating and drinking while the mind is much engaged upon something else. The parts are scarcely quite voluntary, as is proved by its being impossible to make them perform their office when they are altogether dry; and accordingly our knowledge of the position of objects within them derived from their mere sensation is always obscure, and the efforts made in consequence sometimes prove misdirected or fallacious. In drinking it is not necessary that greater efforts should be made than in eating; but from the facility with which fluids glide along, they often present a larger mass, which requires a greater effort to be propelled at once into the pharynx by the organs of deglutition; and as they easily slide into the smallest cranny, they render the closest approximation of the two lips of the glottis, and of the epiglottis upon these again, indispensably necessary; and as the movement of drinking is generally of the continuous kind, the oppression of the respiratory processes which it produces is always considerable, even in health, as is demonstrated by the strong inspirations rendered necessary after a large draught. They must eventually, however, be much greater in hydrophobia, where difficult respiration and irritability of the larynx and fauces are already at their maximum. Besides, in the movement of swallowing, the larynx is drawn upwards and forwards, and the root of the tongue thrown backwards over the larynx, a circumstance which must greatly increase the tendency to suffocation resulting as described; hence the very great augmentation of this spasm while

the larynx is being drawn up. As the disease proceeds, this symptom becomes more severe, and calls in a more extensive train of concomitant evils; of which number are laborious respiration, sighing, vomiting, flatulent eructations, a sense of a ball or pressure on the throat, urgent thirst, a burning pain along the course of the spine, neck, and vertebral column. The increase of saliva at this period seems to arise partly from the vehement irritation of the salivary glands which is produced by these movements, as a similar state occurs in many healthy persons, when induced from anger or loquacity to move the muscular parts in the basis of the jaw with great activity. In other cases, however, the saliva is said to precede the spasm, particularly in animals; and in all such instances it must be referred to the specific effect of the poison upon the salivary organs, a series of glands which, of all others in the body, most readily yield their secretion to a new stimulus. The best authors are agreed that it is the experience of the painful sensations thus produced which in general gives rise to this fear of drinking, which is afterwards, by a too natural process of association, extended to liquids themselves, and finally to polished bodies, to light, to cold, to fresh air, to names or sounds, or indeed to any thing that serves to suggest to the mind of the patient the horrible idea of his sufferings while attempting to swallow fluids. In this opinion we feel ourselves obliged to coincide, as well from the result of our own experience as from the consideration of a number of recently well attested cases, in which the patients not only denied every antecedent dread of fluids, but made many spirited and occasionally successful efforts to overcome that spasmodic resistance which alone prevented their transmission to the stomach. If we add to this the fact of the dread of water disappearing during the intermissions which have occurred in some cases, and in that final remission which occasionally takes place before death, we shall see that the spasm is the chief cause of the dread of water; and that if the latter had depended, as some think, upon a peculiar modification of the mind produced by the bite, it would not be so frequently absent. The disease is now fairly constituted; the patient is tormented with thirst, every attempt to allay which by drinking only serves to bring a new and more severe paroxysm, the convulsions of which often extend themselves to every muscle of the body, whether of head, trunk, or extremities. There are vomiting of a greenish or dark-coloured matter, eructations, inflation of the stomach and bowels, great pain in the region of the diaphragm, restlessness, heat of skin, and sometimes considerable frequency of pulse. The latter has counted as high as one hundred and fifty beats in a minute. In addition to the headach and singular cast of countenance already mentioned, a peculiar brightness, 'a wild and sparkling expression' of the eye, compared by authors to that observed in incipient ebriety, and a retraction of the angles of the mouth approaching to the sardonic grin, and referred to the well known sympathy sub-

sisting between the diaphragm and zygomatic muscles, are symptoms confined to the head and face. The latter is sometimes suffused, sometimes pale, or varied with large, irregular, ruddy spots. A great plurality of testimonies has satisfactorily established that a certain change or alienation of mind takes place during this disease; but in what that alienation consists, how it is to be described, or where it has its origin, are questions which have all been violently disputed. The most general form under which it appears is a certain promptitude of action and loquacity while engaged in conversation, which is chiefly evinced by the patient rendering longer answers and more circumstantial explanations than he might naturally be expected to do at another time; yet his ideas are said to be perfectly coherent, his reasoning just and consecutive. But the susceptibility of the mind also, as well as of the body, becomes greatly increased, and in this point the analogy with incipient ebriety fails, with the exception perhaps of a very few instances. This morbid susceptibility is manifested by a tendency to take alarm at inadequate causes, and to form suspicions without any probable grounds; and, in fact, the dread of water itself and of every thing suggesting the *idea of water*, may in certain subjects be merely another of its indications. High delirium is seldom present except during the extreme violence of a paroxysm, and then but rarely; and as to the states of mental alienation, vulgarly designated by the terms mania and melancholia, they can scarcely ever be said to be present in this disease, however universally the former opinion may once have been diffused. It is fair, however, to remark that the reasoning faculties cannot be altogether entire in a patient who indulges undue suspicion, and who, contrary to previous habit, launches into verbose harangues upon every trifling occasion; for it seems to be the very essence of sanity to perceive justly the relation of its possessor to present external circumstances, which relation is by such persons evidently neglected. We dare not, however, go to the length of proposing for this peculiar susceptibility of mind the term of *lyssomania*, so many patients having expired of this disease without having exhibited the least symptom of suspicion or loquacity. There is still ground for apprehending that their fears are in some instances owing to the vulgar apprehensions of the rough treatment under which the last scene of hydrophobia was till very lately generally believed to terminate. Thus, taking one of many instances, the patient Groves, whose case is related by Dr. H. Maclean of Sudbury, in 1792, had imbibed the idea that "he was to be smothered between beds, and in the most earnest manner entreated us not to shorten his sufferings in this manner." Indeed, only twenty years before, an attempt had been made by the attendants in the Leicester Infirmary to destroy a hydrophobic boy, Nourse, in a similar manner, and they were only prevented from effecting their horrid purpose by the timely intervention of Dr. Vaughan. Groves was a

powerful man, in the prime of life; and when we consider the characteristic timidity of hydrophobic patients, we may well conceive that a very great number must have suffered under this apprehension, without daring to give it utterance. So late as 1814, Dr. Albers of Bremen was sent for by a hydrophobic patient in order to bleed her to death, and thereby release her from her sufferings; and she seems to have considered this as quite within the line of the doctor's ordinary practice. The loquacity, though in most instances the result of the peculiar nervous excitement present, may in others arise from the new and terrific circumstances under which the patient is placed, something like what is often observed in persons led forth to execution; and it is no doubt greatly promoted by the accelerated circulation and intensity of sensation which accompany the hydrophobic spasm. Both are symptoms, however, very generally present, and it is under that view they are brought into notice here.

The whole of the symptoms above expressed may establish themselves in a few hours after their commencement, though in general they can scarcely be said to become so fully developed before the second day; and death most usually happens on this and the third, according to Hamilton's table, although in a considerable number it has taken place after twenty, twenty-four, or thirty-six hours; and in others it does not happen before the fifth day, and in some few instances not before the eighth or ninth day. Hence there is seldom much time afforded for contemplation of the more exasperated form into which they subsequently pass, but yet they have been observed and described by medical writers with great exactness, and have gradually become separated from the fictions with which they were combined by ancient authors. The sense of thirst, and sometimes also of hunger, become much more urgent; there is frequent vomiting of a green or bilious matter, which does not relieve the pain of stomach or the tension of the præcordia. Besides these greenish and black fluids, which are probably different forms of bile, authors have described the matter vomited as sometimes glairy, sometimes cineritious, and sometimes resembling coagulated blood. The patient is tormented with a burning heat and dryness in the fauces; and the saliva, no longer receiving its due admixture of watery fluid, becomes thick, viscid, and adhesive, and frequently accumulating about the glottis of the patient, and thereby threatening immediate strangulation, causes the unhappy sufferer to make every effort to blow it forward out of the mouth. It is the sound made by this effort which produces that faint resemblance to the barking of a dog, and that appearance of froth adhering to the lips of the patient, which have been so absurdly described as characteristic of the disease. Surgeons, who know that suffocation is produced in good health by a little blood from the tonsils being allowed to accumulate about the glottis, will be at no loss to comprehend how this acrid saliva must irritate the sensitive and frequently inflamed fauces of hydrophobic patients, and

make them anxiously endeavour to remove it. Besides, they are often at this period seen to labour under such extreme difficulty of breathing that bronchotomy has been practised for their relief; and it is probably to this cause also we are to attribute the anomalous movement of the cheeks and lips described in some patients, and the occasional presence of black blood in the left side of the heart after death. The restlessness, the tremors, the guttural and general convulsions, return now with much more frequency, and are elicited by the slightest causes; the mind becomes much agitated, and in several cases seems quite unsettled during the paroxysms; impatience of the slightest contact with the skin, of light, and of sound, is frequently present to a remarkable degree; and when the pulse and heat of skin are considerable, a person who saw hydrophobia in this stage for the first time might easily mistake it for phrenitis; but the skin is generally cool, the urine natural, the blood yields no buffy coat, the pain of head is inconsiderable, and the delirium transient. The pulse varies extremely in velocity, but is generally quick, and has been counted as high as 150; it is seldom, though sometimes, strong and hard; and the feeling it impresses on the finger as to fullness, creeping, &c., is by no means uniform. Meantime, the powers of nature are gradually suffering exhaustion, under these repeated paroxysms of action, in which muscle and nerve seem alike to participate. The patient, who usually complains of debility from the commencement, whatever force he may be found to exert during the paroxysm, appears to become rapidly weaker, until at length, after one or more desperate exacerbations, life is extinguished. In a few cases he unexpectedly becomes tranquil, and most of his sufferings subside or vanish; he can eat, nay, drink, or converse with facility; and former objects, associated with the excruciating torture of attempting to swallow liquids, no longer disturb his feelings. From this calm he sinks into repose, and suddenly waking from his sleep, expires. Sometimes, on attempting any new movement, he dies suddenly; but in many cases he is carried off from this deceitful calm by a sudden and violent convulsion. In the great majority there is no calm or intermission, but the paroxysms, becoming more and more violent, at length carry off the patient. The muscles remain rigid long after death, and the eyes in some instances retain their peculiar brightness, and the iris its contractility, till the following day (*Gorcy*); nay, in one case the pupil, which had remained constantly dilated during the disease, returned to its natural dimensions after death.

Such is the most general progress of the disease, but there are many varieties observed to occur in different individuals, a circumstance which has given rise to many controversies. At times hydrophobia intermits, and at others remits. From the histories on record, it would appear that these interruptions tend somewhat to prolong the duration of the disease, but have no distinct effect in rendering it less fatal. This conclusion, however, is not universal, and the

circumstances which lead to these temporary suspensions of hydrophobia are not entirely unknown. The alvine secretion, perspiration, and urine, seem generally to continue in a natural state throughout the disease; but the skin frequently becomes intensely sensible, causing the patient to start or scream with horror on the slightest touch. The settling of a fly upon the surface of the body, the contact of cold air, or of heated air moving in a current, produce the same insufferable sensations and the same tremors. Perhaps the dread expressed of mirrors and smooth objects is rather to be attributed to the patient's associating with them the effects of cold upon this irritability of the skin, than with the torture experienced in the act of drinking. We may probably refer to the same source, the observation of Eudemus (A. C. 23), that the trickling of a tear down the cheek will sometimes excite the paroxysm. In a few instances, however, the skin is hot and dry; in others, it is harsh to the feel, but without heat; and in one or two cases it is described as appearing livid; sometimes it is described as covered with a profuse perspiration. In Dr. Johnston's case, the bowels were confined throughout the whole disease, and so closely constricted was the extremity of the rectum by spasm, that every attempt of the medical man to introduce the clyster-pipe proved fruitless, although made with abundant firmness. In nearly all the cases that have come to our knowledge, the urine was natural, a most remarkable circumstance considering the waste constantly going on from the blood by the saliva, and by the pulmonary and cutaneous exhalations, and the impossibility of introducing a fresh supply of moisture. In a few instances, however, it has been remarked to be scanty, in others of a greenish, and in others of a pale lemon colour. Generally speaking, the organs which excrete this fluid have scarcely been known to be affected with spasm in hydrophobia, although this is a common symptom in hysteria and hypochondriasis, diseases which it resembles in many particulars. In one of Mead's cases, however, (the first,) there was difficulty of passing urine: the patient had "strangury to a great degree, exciting cries on attempting to pass urine; the urine was as well coloured as ordinary." In short, the glandular organs appear to be but slightly affected, and perhaps never primarily in hydrophobia, with the exception of the salivary and lachrymal apparatus. Some persons experience an extreme soreness in the scalp on its being touched, and others, as we have seen, have a similar aversion to contact on any part of their surface, declaring that it hurts them; others experience more or less of pain in the region of the larynx or trachea, during the whole or part of the disease; and some have suffered pain and enlargement of the thyroid gland, generally on one side only. During the latter stages of some forms of hydrophobia, the lymphatic glands around the basis of the jaw became sensibly enlarged. Cases are related, in which the first indication of spasmodic action about the neck does not occur in the

muscles attached to the basis of the skull, but in the root of the tongue, in the muscles originating from the os hyoides, and it is described as commencing by a sense of rigidity and stiffness merely in that position: on looking into the throat, for the most part nothing is to be seen; but in other instances turgescence and the general signs of inflammation are distinctly visible upon simple inspection. Externally, in some rare instances, the larynx, or the thyroid gland, or the submaxillary gland, have appeared to the medical attendants to be somewhat enlarged.

It has already been observed that those bitten by cats have seldom the dread of water, or the difficulty of drinking it to any great degree; so that to many of them the fable of Tantalus, if ever it alluded to hydrophobia, becomes an allegory misapplied. Such is the notion of Dr. Good, who probably omitted the fear of water from his definition on this account; but the proposition is not rigorously true. In Dr. Vaughan's case of a boy bitten by a cat, he "sobbed deeply at the sight of water, turning away with perturbation." Mr. Bellamy also, and the patient described by Dr. White, (*Hamilton*, pp. 340, 430,) were both distinctly affected with the hydrophobic spasm; and perhaps the only reason for this supposed peculiarity in the bite of the cat, and which has induced this learned nosologist to create two new species, 1, the *rabies felina*, with little spasm, and, 2, the *rabies canina*, with much spasm, has been the simple fact that the cases on record of hydrophobia from cats are too few to afford a firm basis for any inference. In other cases there is no nervous agitation, in others no vomiting, in others no tracheal irritation, in others no fever; many have the respiration nearly free to the last; some await their end with considerable tranquillity, their mind being little disturbed during the whole scene: while, besides those affected in the manner we have described, there are others who become delirious from the middle period of the disease.

Finally, it is not the modification of one individual symptom that is to fix the attention of the medical observers in hydrophobia, but the changes in one or other of those great original groups to which we have said each individual must belong; the chills and flushes, the tremors, the excessive cutaneous tenderness, the intolerance of light, of sound, of pungent smells, the preternatural activity and force of action, the tendency to certain motions, as leaping upwards, running backwards, climbing; the facial, guttural, and thoracic spasms; the great increase of muscular force, the general convulsions, and at length paralysis of the limbs; the amaurosis, and mental aberration, are symptoms many in number and various in aspect, but all flowing distinctly from one source, a nervous system irritated and finally exhausted by the action of the poison: the priapism, spasmodic contraction of the cremaster muscles, and involuntary emissions, which occasionally occur, have the same origin. That satyriasis ever attended these last symptoms in the hydrophobic patients of Britain, we have not been able to learn. There

are good reasons for thinking it never did, as being familiarly mentioned by the ancients, it was not likely to be passed over in the great exactness of modern description. French writers, however, assert that it frequently occurs so combined in that country; and the respectable Portal bears witness to his having seen several instances of furor uterinus occurring in hydrophobic women. This is probably another example of variety resulting from the diversity of national education. Many irritations of the nervous centre are known to produce these symptoms, and if they are sometimes occasioned in hydrophobia by spasmodic contraction of the perineal muscles, the origin of that spasm is the same. Neither must it be forgotten that the reasoning powers, the present conversation, and the previous knowledge of a patient, as well as his physical power of enduring pain, will considerably modify all the mental phenomena; and when the fever is vehement, there will be a further change of these phenomena from that cause. The respiratory phenomena must likewise vary according to these leading symptoms; the *sighing* will have more relation to the fever; the *sobbing* more to the nerves. The theory of sighing is well known; but that of sobbing is evidently of the nervous class, and has been traced by Sir Charles Bell to the sole action of the respiratory system of nerves. It is exactly the movement produced by throwing cold water suddenly upon the naked shoulders, and was long since described as such by practical authors. (*Hamilton*, App.) This affection of the respiratory class of nerves lent some countenance to the peculiar hostility of the rabid virus to the eighth pair, to which we have elsewhere alluded.

The changes which take place in the functions of the organs of sense are abundantly curious. At first there is a distinct increase of their power, the exercise of which seems far from disagreeable to the patient himself; and hence the wandering aspect and rapid movements of his eye: he listens to sounds, and detects smells, which no one else can observe. Sometimes he speaks of a disagreeable smell exhaling from the wound, and possibly with correctness, it being no great argument to the contrary that the bystanders cannot perceive it. M. Majendie attended a hydrophobic patient, who, though born deaf and dumb, heard very distinctly during the paroxysms. Neither is the sense of touch at first disagreeable; and one patient whom we attended compared it to tickling. But in a short time they all become affected with pain, and finally with anæsthesia or paralysis; the patient hears indifferently, has numbness in certain parts, the pupil becomes dilated, the sight indistinct, and at length lost. This progress from an agreeable excitement to pain and collapse seems to mark the progress of some mischief accumulating upon the nervous system. The supervention of partial paralysis, paraplegia, and even hemiplegia, tends much to confirm the same opinion; nay, in the case just alluded to there was an universal paralysis, or, in other words, an apoplexy; and

we remarked in our notes at the time, that it differed in no respect from a severe case of apoplexy, except that the stertorous breathing was less.

Nothing can be more various than the different frequency of hydrophobia in different countries and seasons. In South America, Syria, Egypt, and Barbary, it is said to be very unfrequent, and indeed scarcely known; even in Britain, where the population is dense, and the chances of multiplying the disorder correspondingly increased, hydrophobia is a somewhat rare disease; and we may meet every day with experienced practitioners who have never seen it. In the mortality bills given in Dr. Willan's able work on the diseases of London, there occurs only one case in the course of five years; and in Edinburgh there has not occurred a single case in the last twenty-five years. On the contrary, it is pretty frequent in many countries on the continent of Europe, as will appear by the following curious statistical table of the ravages made by human hydrophobia in the kingdom of Prussia:

Years	1810,	1811,	1812,	1813,	1814,
Deaths	104,	117,	101,	85,	127,
Years	1815,	1816,	1817,	1818,	1819,
Deaths	79,	201,	228,	268,	356.*

From this it appears that the deaths in ten years amounted to 1666, or to 166 yearly, which considerably exceeds the number of authenticated cases known to have been put on record throughout the world when Dr. Hamilton wrote his book in 1798. The deaths were most frequent in the provinces of Marienwerder, (228,) and Bromberg, (162.) In Breslau it was 90, in Oppeln 53, in Trier 46, in Aachen 58. On the contrary, not a single case occurred in Stralsund; and it was rare (5) in Dusseldorf and in several other places. Hufeland observes that those provinces in which it is most abundant are contiguous to forests containing wolves, to the forests of the Ardennes, of Russia, and of Poland. Hydrophobia is very rare in Sweden. Odhelius declares that the disease is so uncommon that up to his time, 1777, not a single case had been communicated to the Academy of Sciences. Crete, and one or two other of the Grecian islands, have been described by the ancients as particularly obnoxious to this disease, whilst it was rare in the adjacent continents; but this was probably the mere result of the great number of dogs reared in them, the breed of these islands being celebrated all over the world. It is the salacious nature of this animal, and the absence of all limits upon continents to the extent of his promiscuous intercourse, that gives rise to the difference so long observed between the dogs of islands and those of the main land. In islands, the number of breeds and consequently the number of mixtures have a limit, and in small islands like those of the Mediterranean, a sufficiently narrow one: consequently a character of breed once fixed will run small hazard of

materially degenerating; for every new tendency will be more or less in an intermediate relation between the breed and the medium character of all the other races. It seems not improbable that the innate fierceness and love of independence, with its consequences, suicide, ardour for general liberty, and aversion to foreigners, which philosophers have long imputed to the human inhabitants of islands, particularly those of Britain and Japan, may be owing to a similar circumscription of family intermixture. Analogous facts may be observed in the Celts and Jews; but we omit this consideration to remark that the same insular circumstances that give rise to the peculiar characters of these far-famed breeds of dogs, may also have generated and propagated a tendency to hydrophobia in those animals. In the Manchester Royal Infirmary, which may be considered the central hospital to nearly half a million of population, very few cases of undisputed hydrophobia have occurred within the last eight years, and in private practice we can only hear of ten cases which have occurred during the same time.

Hydrophobia attacks every sex and age without discrimination. Soranus, the ancient methodic physician, had observed it occurring in infants at the breast, and this remark has been confirmed in later times. No temperament, no strength or weakness of body, no mode of existence or habit of life is spared; and, upon the strictest investigation, it does not appear that any one of these circumstances, though they are known so materially to modify even diseases resulting from specific contagion, has ever produced the least modification of the symptoms in those attacked with hydrophobia. It seems, in particular, to invade alike every class of society: the superior intelligence, cleanliness, and comfort, of the classes raised above the necessity of daily labour, is found to afford them no security; and, considering that their exposure to the exciting cause must be considerably less, there appears to be a full proportion of cases occurring in such persons put on record in the writings of physicians. It must be observed, however, that a great number of those who have been bitten, escape the disease, and that this good fortune cannot be without a cause. Blacks are obnoxious to hydrophobia as well as whites, but in what proportion to the latter has not been ascertained. Some have inconsiderately asserted that men of the Arab race are exempted from its ravages; but this is sufficiently confuted by the familiarity with which Avicenna, and other Arabian physicians speak of the disease.

In studying hydrophobia we must avoid a source of error from which false reasoning and many false facts have flowed from the time of Cælius Aurelianus; who seems entitled to some praise for the invention of a sophism that has been so much employed by his successors, and so well received by the mass of mankind. "If Homer," says he, "knew of dogs, and of the hydrophobic disease to which they are subject, he must also have known of the hydrophobic disease of man; for the dis-

* Edin. Med. Surg. Journ. 1824.

ease of the dog is the cause of the disease in man; and if he knew of the cause of the disease, he must of necessity have known the disease itself; for where the cause was present, the effect would naturally follow." By a parity of reasoning it has been inferred that wherever dog-madness is, there human hydrophobia must also be; that the climates which produce the one must produce the other, and that the symptoms which are produced in the one must be produced or imitated in the other. It is chiefly owing to these extravagant conclusions that we are often unable to discover whether an author is speaking of the disease in man, or of the disease in dogs; that we find all the fabulous symptoms imputed to the mad dog by the first writers, described in the hydrophobia of man by medical authors comparatively modern; and that, up to the present hour, the influence of climate or local position is supposed to exert some influence on the production of this disease. Two things, however, are clear; first, that a place may be for a length of time free from hydrophobia, and yet suffer greatly afterwards from the direct demonstrable importation of that malady; and, secondly, that the disease may be raging amongst the canine race of a district, where formerly cases of human hydrophobia have occurred, and do afterwards occur; and yet from the activity of the police, chance, which gives up only every twenty-fifth person to the confirmed disease, and another series of chances comprehending the confinement, detection, or death of the animal himself, may combine to render the canine disease devoid of all bad consequences at that time, without our being forced to suppose that climate or atmosphere have in the smallest degree interfered. As these facts seem important, we shall illustrate them by a brief example. In 1798, Dr. Hamilton assures us, on good authority, that canine madness had not been seen in the island of Jamaica within the last fifty years.

In 1822, that excellent observer, Dr. James Thomson, of St. Thomas in the Vale in that island, put upon record the following decisive facts regarding the same subject in the Edinburgh Journal. Dr. Thomson had an opportunity of observing the cases of two hydrophobic patients in Jamaica, whose malady resulted from the bite of rabid animals. Upon dissection he did not omit the spinal marrow; but except slight inflammation of the throat, not the smallest appearance of disease was manifested. Neither did he find any thing in the bodies of three different animals which died mad. Simple heat will not create the disease, as it is not more common in tropical regions. Some years ago almost all the dogs in St. Domingo were infected, from the bites of some rabid animals that were brought from America; and it has, since that period, been repeatedly traced to infection from that quarter. It has also been repeatedly communicated to the race of dogs in this island. The dogs kept for the destruction of rats upon sugar estates, are occasionally seized with madness. Dr. Thomson once saw an instance of a goat bitten

by a dog, and where mercury was given. The poor creature ran at the mouth terribly for some days; but soon afterwards died mad. He has been informed that herds of swine become occasionally mad, biting and tearing each other. It is obvious, therefore, that the disease has been imported into Jamaica since 1798, at which time it is supposed the island had enjoyed an immunity from it of fifty years; and this immunity, which authors had attributed to climate, was in reality the effect of accident. Insular situation rendered it easy to exterminate the dreadful visitant, and a large period of freedom from its ravages succeeded.

What relation the disease may have to the different seasons of the year, or to various modifications of the weather, will be more properly considered amongst its causes.

Causes.—The most careful investigation by the anatomist has hitherto discovered nothing in the dissection of the bodies of those destroyed by hydrophobia, which throws the least light upon the theory of its cause. The bodies of many patients who expired under frightful sufferings, have not exhibited the slightest indication of disease. In others, an early and careful examination of the fauces discovered no morbid appearance during life; and the few organic changes which have been described in other cases are too various in locality and degree among themselves, and being mere traces of inflammation, are too easily explained as the consequences of the violent straining, and spasmodic action of these parts, and of the acrid secretion, or halitus, whose combined irritation they undergo during the latter part of the disease, to enable us to deduce from them any conclusions as to the seat or the mode through which the exciting cause works out its fatal effects. The details, therefore, afforded by pathological anatomy, we shall do better to reserve for another place; and we now proceed to consider the causes of hydrophobia in their triple relation of *pre-disposing, remote, and proximate*.

With respect to predisposing causes, we have nothing but the most loose analogies: persons of the nervous temperament, and of a feeble habit of body, and melancholic and irritable individuals, are occasionally liable to obstructions of the great functions of the throat, breathing and deglutition; and these impediments appear universally to be of the spasmodic kind. The globus hystericus, the dysphagia sicca, the hydrophobic spasm, spasmodic croup, and even spasmodic dysphagia, are all members of this family, and exhibit the common character of supervening suddenly; not unfrequently indeed from mental emotion also, or gastric irritation, particularly dyspepsia. But these are merely evanescent accidents, and have no right to be considered as having the same origin with the terrible spasms of human hydrophobia. On the contrary, we have already seen that the hydrophobia of man occurs in every possible temperament, age, and habit, and it is therefore most illogical to infer that they have any thing

in common in their origin. In plain truth the excitement which produces the spasms in question, produces the same effects in the most robust, sedate, and fixed of human constitutions; and, taking their own view of the matter, who is it, of all such speculators, that would dare to assert that he knows the exact measure of force exerted by the cause of hydrophobia? Or that he states on demonstrable grounds, that there ever exists in human bodies an irritability too small in degree for it to produce its specific effects? We say then, that the notion of a nervous or melancholic temperament predisposing to human hydrophobia is an *ex post facto* observation, drawn from what is seen in the symptoms after the disease is formed, and not a genuine clinical remark chronicled in the latent stages, and confirmed by comparison of cases. The few other predisposing causes that have been occasionally alluded to are too improbable to deserve notice in the present day; being those causes which have been noticed as producing the non-rabid hydrophobia, which are afterwards to be disposed of, and which may very well be allowed to remain in the class of exciting causes of that distinct species, till they have been shown to act as predisposing causes of rabid hydrophobia; an assumption altogether gratuitous, and of which at present there does not exist one instance upon record.

As we advance to the *exciting* causes, however, our information acquires a more satisfactory character. That the bite of a dog, labouring under a particular form of madness, is often succeeded in man by the symptoms above described, and in animals by a disease remarkably analogous, and equally fatal, is a proposition which is confirmed by the testimony of all ages and nations, and has never been called in question by any respectable writer. But numberless, and many of them indeed extremely interesting, questions have arisen out of this admitted fact, and are still occasionally proposed for our solution, with regard to the time, manner, and circumstances under which the apparently trifling injury, which precedes, produces the fatal consequences which follow. Does the disease ensue from the influence of fear alone? And, if so, is this fear created by the terrible appearance of the animals, by the prejudices of the patient, by the apprehension of the medical attendant, or by all these terrors acting together? Is it the simple result of laceration extending, as in tetanus, its irritation from the part wounded to the more susceptible portions of the nervous and muscular system? If so, are we to consider it merely as a form of tetanus, or rather as a different disease originating from a parallel cause? And in either case, would the claws, or other rigid parts of the animal produce similar effects by a scratch? If so, why do the symptoms of hydrophobia differ from those of tetanus? Again, is the disease communicated by a poison or virus which passes into the wound, during infliction of the bite? If so, does it come from the saliva or the tooth, or is it the saliva itself in

a morbid state? Is it absorbed into the system, or does it remain in the wound? If absorbed, does it modify the whole blood and secretions, or merely the secretions of the saliva; and does it imbue this in man with the power of communicating the disease? If the virus is not absorbed, by what mysterious operation does it induce distant parts of the system to create a similar virus, and at length to undergo such vehement and fatal action? Into what condition is it passing during the state of recrudescence; and how does it bring to pass the phenomena which constitute this state? How long or how short a time may it remain latent in the human system? Can it act by inhalation or mere absorption? Can man communicate it to his kind, or to other animals? These are questions which, however numerous, require to be considered in the etiology of the present disease.

We have already shown that the disease does not arise from the influence of fear alone, nor is it ever imaginary. The rabid animal is often quite unsuspected when he inflicts the wound; and in other cases the patient is in a condition incapable of appreciating danger, or of connecting in his mind the former injury with his present feelings. The case of Richard Brown, in the *Edinburgh Journal* for 1810, affords important testimony to this effect. To the inquiry, is hydrophobia merely a tetanic affection, originating in the laceration produced? A fuller answer will be returned in the diagnosis; but order meanwhile makes it necessary to remark, that tetanus and hydrophobia must either be the same or two different diseases. If they are the same, where is the locked jaw and tonic spasm of tetanus in the latter? The frothy, overflowing saliva, the thirst, vomiting, clonic guttural spasm, tremors, and mental aberration of hydrophobia in the former? In short, what medical man ever mistook one for the other since the days of Democritus? If they are different diseases, why attempt to class them together under the same appellation? No man pretends to explain distinctly how a lacerated wound excites the phenomena of tetanus; and we should be committing the old logical blunder *ignotum exponere per ignotius*, if we coincided with the attempt to explain the operation of the cause of hydrophobia, of which we know so very little, by the theory of tetanus, of which we know nothing. If it be said that there is an analogy between the exciting causes, the spasmodic paroxysms, and the fatal results of the two diseases; it may be answered that this analogy entirely fails in the diagnostic particulars above enumerated; and perhaps still more essentially in the fact, that tetanus never engenders madness or a desire of biting in the lower animals, and is never communicated by a bite from one to another. This last circumstance renders it impossible for us to consider hydrophobia as produced and matured by any series of proximate actions parallel to those which produce tetanus. By the argument of exclusion, therefore, we are obliged to admit the principle of a virus, for

we know of no other mode, and we shall find that, besides this necessity, the absolute existence of such a virus is all but demonstrated by many positive analogies. The saliva of the animal inflicting the bite is evidently changed in its nature, being morbidly abundant, viscid, and frothy; wounds inflicted through clothes are less frequently followed by the disease than in those which occur in bare parts, as the hands and face; thus in Oldknow's case above quoted, no recrudescence took place in the scrotum or thigh, because, in wounding these parts, the teeth of the animal had been wiped as it were by passing through the person's clothes, before they could reach the soft parts within; but it took place in the hand, though the part last bitten, because the animal, which had been forced to let go its former hold only after using considerable violence, had time to shut his mouth and wet his teeth again in saliva, before inflicting the wound. Introduced by a wound into carnivorous animals, it evidently reproduces a similar saliva wherever it excites the disease. In one omnivorous animal, man, the same fact has been proved by Magendie, by means of injection; and from the testimony of Dr. Thomson above quoted, and many other writers, the same thing seems probable with regard to another, the hog, when introduced by a bite; and the symptoms of the malady ensuing, with the addition of the biting tendency, peculiarly resemble those which take place in man. Amongst the herbivorous animals a large salivary apparatus is necessary for their food, which does not undergo its ultimate chymification in the first stomach; and it is not impossible that the changes produced upon these organs by the rabid poison may be too small to generate the new virus. After all, the virus may be there, but in too dilute and feeble a state to manifest itself in the few rude experiments which have yet been made by physiologists upon this subject. There does not, however, appear on record any indubitable case or history in which hydrophobia seemed to be communicated from one herbivorous animal to another; but this does not weaken the analogy to virulent poisons observed in the hydrophobic bite of the other two classes. Again, the effects of the bite, like those of a morbid virus, for the most part, manifest themselves within a certain time after its infliction, by far the greater number becoming ill between the thirtieth and the sixtieth day, and a great majority of these again about the fortieth, the day before, or the day after. Every morbid virus, however, presents irregularities in the time of its manifestation, and that which remains the longest latent, by affording time for the occurrence of a greater number of causes for its evolution, must be that which presents the greatest number. Hence it is, that the syphilitic and hydrophobic virus exceed all others, and nearly coincide between themselves, in this irregularity. Nay, the fact that dogs frequently communicate the disease by a bite during this latent period, seems to evince that there is a

morbid assimilation in progress long before the appearance of the symptoms; a circumstance which is perfectly in accordance with the idea of a virus; but which cannot well be understood on any other supposition. The train of symptoms occurring in the wound itself, which we have ventured to comprehend under the term recrudescence, correspond very well with the idea of a virus. Why should the wound, after a considerable lapse of time, again become painful, red, and swollen, unless some cause of irritation still remains lurking within it? Why should it re-open after such an *increased* action, of which augmented adhesion is understood to be the only natural result? Wounds re-open in scurvy, purpura, pest, and putrid fevers, because the weakened vessels easily part from each other at their points of inoculation; and cannot, moreover, deposit new matter in proportion to the rapidity with which the recent texture, now almost dead matter, is taken up by the absorbents, and the bond of union is thus first destroyed by the absorbents from within; just as it would certainly be the first to yield to the action of escharotics from without. But the state of the parts seems totally different here; and that they are ultimately separated from each other by the irritation of some matter lodged within the place of the wound, seems proved by the peculiar nature of the ichor discharged, by the eruption which sometimes takes place around the cicatrix at the same period, and by the livid colour frequently observed to surround it. The latter, it is believed, owes its frequent appearance about specific sores to their acrid matter inflaming and contracting the valves of the contiguous veins, by which it is absorbed into the system. Thus, though we cannot give ocular demonstration of hydrophobic any more than of any other virus, its existence rests exactly on the same foundation as that of all others. This virus cannot proceed immediately from the teeth, for their flinty sheath of enamel remains unchanged during the whole disease, and they present no pores, canals, or openings through which the noxious matter may distil, no poison bag as in the fang of the serpent. The saliva, therefore, is the immediate vehicle of the poison; but it does not follow from hence that the salivary glands themselves are its primitive source. Troiliet contends that the virus proceeds from the bronchial membrane of the lungs, which is in a state of inflammation. The tonsils too are known to secrete a matter very different from the ordinary appearance of saliva; and anatomy in many cases detects a very fetid product in the follicles of the arytenoid glands of the larynx, which is believed to be the cause of offensive breath during life; and the breath of hydrophobic patients is often observed to be extremely disagreeable. The lungs are in a state of morbid action during a great part of the disease, and the effects of the impingement of acrid halitus from these organs upon the membrane of the fauces become very manifest in certain cases, as in the symptomatic aphthæ of phthisis pulmonalis,

and the blistered chops which frequently precede mercurial salivation. The virus, then, may either be an addition to the saliva, analogous to that of oxalic acid, which Brugnatelli discovered in it, or it may be the whole saliva morbidly changed; and, at present, in a state of animal chemistry that cannot distinguish between the bland mucilage of gum arabic and the most virulent poison of serpents, the decision of this question cannot be of much importance.

"Is the virus absorbed into the system, or does it remain in the wound?" We have above observed, that if the hydrophobic virus is absorbed, it does not specially affect to find its way into the body through the medium of the lymphatic system; it may enter the circulation still more rapidly however by means of the veins; and the lividity described about the cicatrix at the commencement of the disease seems to point out this as its actual course. To those who suggest that the poison may remain confined to the part, and thence impart, from its malignant focus, a portion of virus to the blood as it circulates through it, till the whole is imbued, it may be answered that, though the suggestion is possible, we know of no fact, and see no analogy in its favour; whilst, on the other hand, it is matter of familiar observation that all other poisons, under the same circumstances, are rapidly absorbed, and may in many instances be prevented from producing their specific effects by mechanical impediments interposed in the course of absorption. This last analogy is also fatal to the ingenious suggestion that the poison may remain in the part, and by nervous sympathy, or, in other words, by irritation communicated from thence along the nervous system, may dispose that system to produce all the morbid phenomena which constitute the disease, and the vitiated poisonous secretion among the rest: just as we perceive in hysteria, proceeding from the topical irritation of worms, or in the non-rabid species of hydrophobia. In short, a virulent specific poison inserted into a wound, and producing, by absorption, convulsions, fear, contagious secretions, and death, is not only an ordinary, but an almost universal event; but a poison of the same character that should lurk in a small corner of the patient's flesh, obstinately resisting all the powers of absorption for months, and finally, without departing from thence, create a malignant poison capable of reproducing itself through thousands of living beings in succession, would be a fact entirely unprecedented; and as it has not been proved to have happened, is therefore at present only a supposition extremely improbable. There remains, therefore, no just or tenable ground for believing that the hydrophobic virus enters the system in any other way than through the ordinary course of venous absorption. To the questions arising from this admission, we can only attend with propriety when considering the *proximate* cause or *theory* of the disease.

The dog and cat, and animals closely allied to them by natural characters, have alone been proved, by correct observation, to possess the

power of communicating this disease. The fox and the wolf are the kindred of the dog; and these, with the latter and the domestic cat, are all the animals which appear upon credible testimony to have produced a genuine rabid hydrophobia by their bite. From all the examples of which the history can be believed at present, it does not appear that age, sex, or variety of breed, or other corporeal circumstances, exert any influence with regard to the disease in these animals. It is true that in Mr. Gillman's account of the death of a sow and her two pigs, all bitten at one time by the same mad dog, whose disease on dissection he fully ascertained, age seemed to have some effect. The pigs were seized respectively on the tenth and fourteenth days after the bite, and the latter died three days after; while the sow was not affected till the twenty-seventh day, and struggled with the disease for five days before she expired: but there are other cases directly the reverse of this result. Indeed the external circumstances which are generally supposed to favour or actually to cause its production in those creatures, are far from being unscrupulously admitted by medical writers. Hunger, putrid food, confinement, violent treatment, great atmospheric heat, great cold, suppressed salacity, checked perspiration, the growth of a peculiar hydatid or worm under the tongue, intestinal worms, epidemic contagion, want of water, self-generated contagion, have all been assigned as causes of the appearance of hydrophobia among animals. With regard to hunger, it is known that the pangs of this state induce a high degree of fury in the wolf, but this recedes when his famine is allayed. It is not hydrophobia, and it does not even appear that the dog, whether domestic or wild, even when dying of hunger, exhibits the same fury. Finally, by far the greater number of cases occur in dogs and cats that are highly fed and pampered. Putrid food seems an aliment as natural to the dog as to the vulture or maggot. The greater number of dogs are lured to it from afar by the odour, and feed upon it with delight. The great majority of dogs kept in kennels are fed upon nothing else; and if we except a chance of the disease running through a kennel when once it occurs, hydrophobia is not very frequent among dogs so preserved. Add to this, that many tribes of mankind, as the sturdy natives of Kamschatka, who abhor all food that has not been some time putrid, are yet far more healthy than others on the same parallel, as the Esquimaux, who eat their victuals fresh; and the undeniable fact that favourite lap dogs and favourite cats, whose taste has long been rendered too nice by indulgence to eat putrid meat of any description, do yet very frequently become mad, and communicate by their bite hydrophobia to man, and rabies to other animals. Great abundance of carrion, however, by congregating a number of dogs from all quarters, whether healthy or infected, must greatly tend to disseminate the malady. The same must be the result of confinement, where many dogs are

kept within the same kennel; and there is very competent authority that the bites of a rabid animal thus enclosed amongst others, may often be traced through a great part of their number, although they are not all seized with the disease, and experience has not proved that confinement usually becomes the exciting cause. It sometimes happens, that dogs suspected of hydrophobia undergo very cruel treatment, but this is more frequently after than before they have manifested that irritability, snappishness, or fury, which are generally deemed characteristic of the disease. By far the greatest number, however, of those affected have suffered no violence from man, and it seems much more probable that in almost every instance they derive the fatal poison from infection communicated by the bite of another dog already diseased.

The most common notion respecting the origin of hydrophobia in these animals is, that it is excited by great atmospheric heat, as for example by that of the dog-days; and hence the annual panic in our own and most other countries, the tying up, muzzling, and killing of dogs, and many other sanitary regulations of police during the hot season. That absolute heat will not of itself determine the appearance of hydrophobia among animals has been already established, from the rare occurrence of the disease in tropical countries. Still there is no reason why autumnal heats should not increase the frequency of the disease in more temperate regions; and the consonance of general opinion with the notions of most writers seems to favour the idea. M. Trollet found the dates at which 114 different dogs had become affected with the disease to spread themselves throughout the whole circle of the year; but the most considerable of them were comprehended in the months of May and September; on the contrary, they were fewest in January and March. The dog loves heat, and delights to saunter about or lie half asleep upon the ground out of doors in warm weather. Hence many more strange dogs are brought into contact with each other, and the chances of infection multiplied; while the excitement produced by the heat may perhaps render them less cautious than ordinary of meeting each other. In point of fact, however, a general register of cases is said to exhibit the disease occurring pretty uniformly through every range of temperature, and every season of the year. Hildenbrand and Roserus conceived that the extreme excitement which in this animal prompts the venereal appetite, disturbs the nervous system so much as to induce a degeneration of the saliva, a change which takes place easily, because the dog never sweats, and consequently the fluids are carried towards the mouth in much greater quantity in this than in other animals. This notion has received some support on the continent,* but it is not easy to see how a state of excitement, which is common to all animals, should produce a specific af-

fection in so few species, and in these again only in a very few individuals; for by far the greater number of animals become mad by having been bitten by other animals. We had supposed, indeed, that the idea of spontaneous hydrophobia had been long since exploded, for the simple and obvious reason that it cannot be proved ever to take place; for we have not yet ascertained all the circumstances under which hydrophobia may be communicated in animals, nor how long the disease may be dormant in their system. So that we should never be safe in asserting that any case was spontaneous, or had arisen without any external cause. Moreover, it is still strongly disputed, whether, from simple irritations within our system, contagious disease can in any case be propagated. Without examples and without established theory, therefore, the notion of the spontaneous origin of hydrophobia, originating at times in the same manner as typhus is supposed to do, from some internal actions, must, like the origin of all epidemics, be referred to the obscure chapter of medical hypothesis which treats of the general origin of diseases. With regard to want of water, no such privation is suffered by a vast majority of the animals from which the disease seems to proceed; and as to the worm under the tongue, it is an anatomical delusion.

We have already alluded to the false, though very general conclusion, that hydrophobia, because it always originates from the same cause, ought always to manifest the same symptoms in whatsoever species of animal, or whatever individual of these species it may occur. Every day's experience refutes this fallacy. The precepts of the Baconian philosophy of induction now triumph over the ancient, *a priori*, method of conjecture in every question of science; and in the present disease, by enforcing the results of strict observation, have banished from the histories in which it is recorded those imaginary analogies by which, however specious, they were formerly defaced. But the variations of symptoms brought into view by this improved mode of investigation are so numerous and discordant, that the causes of these discrepancies between the forms of the disease as it occurs in different species and different individuals become a fair and legitimate object of inquiry. First then, it must be observed, that in the appearance of the symptoms some modification may be expected from the degree of sagacity or intellect of the animal affected. Man, who is distinguished over all other creatures by the superiority of his reasoning faculties, and by the power of correcting morbid associations by the employment of these faculties, may be well supposed to resist the establishment of many diseased combinations of ideas, originating in the perverted sensations peculiar to this malady, which would instantly have undisputed possession of a quadruped. And thus also in man himself, with adults, so long as there is no delirium there is little or no fear of water, or of circumstances suggesting the recollection of water; but when the delirium

* Sprengel. VI.

is once become high, the person no longer suffers merely from the pangs endured from attempting to drink, but associates in his mind those tortures with the fluids which produce them or matters that resemble them. On the other hand, infants, weak-minded persons, young and stupid animals, seem to yield to this very natural association, and further to combine it with self-preservation almost from the commencement of the hydrophobic attack. On the same principle, it is hardly to be supposed that a carefully educated and sagacious dog will so readily yield to the suggestions of these morbid feelings, or so soon resort to the means of self-defence which in brutes are inseparably combined with attempts to destroy the object of their fears, as would a wild and masterless animal; and this is probably the reason of that indiscriminate fury observed in the mad wolf, now believed by naturalists to be merely the dog run wild, as it probably is the cause why hydrophobia is so often communicated by dogs of which no one knows the owner. Hence it is that wild dogs in this state fly at all things in their way and tear them with violence, while the fully domesticated dog, unless highly provoked, rather snaps than tears. In a most formidable experiment performed on a little favourite dog, in the year 1826, Mr. White, of Brighton, found it no easy matter to induce the animal to bite his arm, although it was so far advanced in the hydrophobia as to die in a day or two afterwards. This may also afford an explanation why many dogs lap water, and even swallow it for a considerable part of the disease; whilst others seem to be completely deterred from it by the great pain it occasions. Thus the sow and pigs described by Gillman, would not swallow fluids, but showed no aversion to the sight of water, although the sow, in addition to the extreme irritability of surface which they all manifested, became subject to that panaphoby, or universal alarm, in which many of the ancients believed the essence of hydrophobia to consist; the older animal thus having sagacity to form an association between pain and consequently danger, and the contact, sound, or approach of external agents which produce them; while the younger ones did not seem to form the same combination. Besides the influence of sagacity upon the mode of avoiding pain and danger, something may also depend on the physical structure of the throat: the pharyngeal spasm does not always constitute the whole difficulty of swallowing; there is very frequently joined to it a feeling of immediate suffocation, and a terrible oppression of the whole respiratory functions, somewhat resembling the worst forms of asthma. When these are wanting, the patient may be more easily enabled to overcome the spasms of the pharyngeal muscles; when they are present, he will be deprived of this power. Finally, this effect may be considerably modified by the force and direction with which the pharyngeal spasm happens to bear on the opening of the larynx; and all the results may be greatly modified by the state of augmented sensibility,

or by the absolute inflammation, perhaps, which exists in those parts.

Having premised these sources of variety, we shall briefly state the symptoms which generally appear in the dog; and which are, after all, abundantly akin to the symptoms of human hydrophobia: but as a great deal of error, and certainly little benefit has hitherto been derived from their study, we shall, in a dictionary of human diseases, consider ourselves entitled to treat the malady of the dog with great brevity, and to pass over that of the other animals in perfect silence. Sometime before the hydrophobia makes its actual appearance in the dog, he exhibits some singular departure from his ordinary habits, such as picking straws, threads, or small bits of paper, from the floor; licking the noses, &c. of dogs, or other animals with which he is domesticated; becoming suddenly attached to animals formerly regarded with indifference; licking cold surfaces, as cold stones, or cold iron. He is observed to be shy, lonely, and irritable, he avoids the approach of other dogs, and sometimes of man, and appears to be less eager for his food, or altogether to neglect it; his ears and tail frequently droop, his look is suspicious and haggard, and sometimes from the very commencement there is a slight redness and watering of the eyes. In a short time saliva begins to flow from his mouth, and passes by degrees into a viscid foam. Respiration is difficult, and performed with panting; the tongue hangs out of his mouth. At this period inspection of the fauces often shows them to be red and inflamed. He has fever, the skin is sensible to the touch, but he still obeys the voice of his master, though now easily provoked to snap at other objects. In many dogs the signs of fury never rise higher than this; but in all there is a repugnancy to control, and a readiness to be roused to extreme rage on the appearance of a stick, whip, or other instrument of punishment; and all attempts at intimidation only serve to increase their rage. Nevertheless, indiscriminate aggression, and unprovoked fury are occasionally to be observed determining all the motions of the rabid dog; he flies at every creature he meets, bites all the dogs, and gnaws the wood of his kennel; and when admitted into a field where sheep, goats, cattle, hogs, geese, or other timid unoffending animals are collected, he tears and pursues every individual of the flock he can approach. The cat is an early object of his rage, and even the horse and elephant have not unfrequently sunk under its baneful effects. Vomiting frequently precedes or accompanies the disease, the respiration appears laborious, tremors are frequent, and the animal is at length destroyed apparently by convulsions. Inspection of the dead body exhibits, with the same irregularity, phenomena entirely similar to those detected in the bodies of the victims of human hydrophobia. It is generally believed that the latent period is shorter in dogs, and indeed in most animals, than what it appears to be in man, but this point is not very well ascertained, and there is abundance of evidence

of the poison having remained in the dog for several months before the disease was produced. Nay, it seems pretty certain that he has frequently communicated hydrophobia to man and other animals, during this apparently latent period; a circumstance which shows that the virulent assimilation is even then going on in the animal's fluids; and suggests great caution in our intercourse with these creatures.

Many have asserted, from Aurelianus downwards, that dogs occasionally communicate hydrophobia to man, to their own species, and to other animals, by their exhalation and saliva alone, without inflicting a bite. To inspire the visible vapour they exhale, to receive their saliva upon the skin or into the mouth, even to be scratched by their nails, or by the nails of a cat, has been supposed to be sufficient to induce the disease. There are certainly a few cases related of hydrophobic patients which seem to come under this description; but as has been well observed by Dr. Bardsley, it is much more probable that, in such cases, some small portion of the cuticle had been deficient at the part with which the saliva came in contact, and thus afforded all the facility of a wound to the conveyance of its poison into the system. The ancients were well aware of the possibility of this, for Celsus observes that the integrity of the lining membrane of the mouth is necessary to the operations of the *Psylli*; and Dioscorides expressly orders those who were to suck out the poison of a rabid dog, first to wash their mouth with astringent wine, and afterwards to lubricate the cavity with oil. With regard to dogs, Mr. Meynell observes, that such of them as have been thought to become affected merely by the contagion of the same kennel, will generally be found, upon minute examination, to exhibit the marks of bites, although concealed by the hair from ordinary observation. With regard to the effects of a scratch, these resolve themselves into the great probability of part of the saliva of the rabid animal having been introduced by the claw which produced it, or having afterwards fallen upon the open wound. In fact, both dogs and cats do very frequently present their foot to the head or mouth, when affected by any uneasiness in that quarter; and they frequently rest themselves with their head reclining upon the fore paws. All such cases, however, are comparatively rare, and there is reason to suspect that many of these histories were examples of non-rabid hydrophobia. From what we know of the great absorbing powers of the lining membrane of the stomach and lungs, it seems not improbable that the poison, if introduced into the saliva, as by kissing a rabid animal, by admitting pieces of cloth, leather, sticks, and the like, impregnated with the same saliva by its bite, into the mouth, the venom might find its way to the stomach and even to the trachea and lungs, and thence, by absorption, be received into the system; and there are some very positive testimonies on this head extant among the older authors; but nothing satisfactory of the kind has been observed during the last two centu-

ries; and we feel ourselves compelled to pause before we admit the inference. The same caution must be observed with regard to the many animals, in addition to those above mentioned, which have been named by medical writers as the propagators or victims of hydrophobia. The camel is alluded to by Aristotle; the leopard, the bear, the horse, the ass, and the game-cock, are mentioned by Aurelian, as animals propagating the disease; Penada (*Saggio*, &c. 1793,) has recorded a case of hydrophobia resulting from the bite of an insect; and the lion and tiger are vulgarly believed to be capable of producing the same effects. Later investigations seem to show that the herbivorous animals do not easily communicate the disease; but the whole evidence adduced is jejune and meagre, and the paucity of cases of communication may entirely result from the pacific disposition of such animals. It is the nature of the carnivorous to be easily roused to rage, combat, and violence. The author of nature has made them so, because by combat and violence he hath destined them to support their existence; but the pacific races that crop the flowery mead, and participate, without resistance, in the bounteous repast with which they are every where presented, have neither habits nor motives which febrile or nervous irritation might prompt into violent action: and into them the same great author has instilled fear only as a motive of flight, seldom as a motive of aggression or resistance. Hence probably, the extreme paucity of their bites altogether, and the assertion that they never reproduce the disease; an assertion which we look upon as calculated to diminish circumspection, and to inspire more confidence than is warranted by the evidence upon which it is founded: we wish that in hydrophobia no other conclusions had been originally drawn from such slender premises, and afterwards expanded into general laws.

It would be of much importance to ascertain, out of a given number of persons bitten, the actual proportion that become affected with hydrophobia. It is difficult, however, to come at any thing like distinct truth upon this point apparently so obvious; for the dog is either immediately killed or tied up, and, consequently bites only a small number, or he runs wild in the country, so that the number of his victims cannot be ascertained. Mr. J. Hunter, however, asserts that he knew an instance in which, of twenty-one persons bitten, only one became affected with hydrophobia; Dr. Hamilton seems to think that one out of twenty-five becomes affected. In 1780, a mad dog in the neighbourhood of Senlis took his course within a narrow circle, when he was killed, after having bitten fifteen persons, of whom three afterwards died of hydrophobia. The French government ordered the most eminent physicians to resort to the spot, examine the cases judicially, place the patients in hospitals, &c. so though the original number is too small to warrant a strong inference, yet it presents the proportion of the number bitten to the number ultimately

infected in one instance with exactness. At Brive, a wolf bit seventeen persons, and of these ten died hydrophobic.

The causes which are said to produce the non-rabid form of hydrophobia, having no great connexion with each other, and being incapable of inducing a successive propagation of the disease either to animals of the same or of a different species, they cannot be supposed, as yet, to have all come to our knowledge:—

1. Superficial wounds, particularly of naked and prominent parts.
2. Nervous irritation of various kinds.
3. Violent intermittent fever.
4. Injuries of the brain and spinal chord.
5. Morbid conditions of the stomach.

The symptoms of the disease induced by these causes do not differ materially from those which result from rabid hydrophobia, and we therefore supersede the unprofitable labour of repeating a detail of these indications. Whoever wishes to consider them minutely will find the particulars of many cases, at great length, in the article *Hydrophobie* of the *Dictionnaire des Sciences Médicales*, and the same condensed, we may be allowed to say, not with great skill, in the *Dictionnaire de Médecine*. Perhaps the best case of the kind on record is that of Lindsay, which occurred from hunger, excessive labour, and mental anxiety, and has been described with great care by Dr. S. Bardsley in his valuable *Inquiry into the Origin of Canine Madness*. It may be remarked that Lindsay must have long laboured under hypochondriasis; for a man that could remain, as he relates, from 1782 to 1794, in the constant dread of his family dying of hunger, without having once suffered it in all the twelve years that intervened, either wanted the usual powers of generalization common to other men, or was no stranger to the disease characterised by a *metus mortis a causis non æquis*. Lastly, the symptomatic forms of hydrophobia must, in a great measure, be referred to their nosological arrangement given above. We do not hold ourselves answerable for a disease, more or less than appears there, having exhibited symptoms of hydrophobia. Observation cannot yet be complete in this respect; and it is certain that our means of judging of the veracity and discrimination of writers describing such cases are very far from being in that state. They are quite unimportant as regards idiopathic hydrophobia; because hitherto no connexion has been established between them; and it is seldom that the disease in which symptomatic hydrophobia originates is better understood than hydrophobia itself. It follows that the only proper place for the consideration of such anomalous symptoms is under the disease in which they arise.

The proximate cause or theory of hydrophobia demands particular attention. Empirical trials, of which the practitioner often thinks but too highly, confounding what succeeds with the ordinary progress of nature, powerfully modified by external circumstances, have held out no flattering unction to human vanity here. Every thing has been tried, and every thing

has failed. And unless reason shall discover so much of the theory of hydrophobia as enables us to resist the evil or counteract its commencement, the malady must be given up as incurable; as one certainly for which there is no longer any hope from experiment. It will not be much to the profit of the reader, however, to record every extravagance which may have escaped the profession during two thousand years of ceaseless speculation upon this topic. We shall, therefore, content ourselves with chronicling a few of the most remarkable opinions that have come down to our own times, several of which have been adopted by different sects in the medical world.

Democritus	B.C.	400
Gaius, brain and motor nerves, 8th pair		200
Asclepiades, stomach		105
Artorius, stomach		30
Themison, thirst and strictum.....		30
Artemidorus, in the stomach		30
Dioscorides		30
Celsus		18
Aurelianus, deficient moisture	A.C.	230
Galen		230
Mead, fermentation of nervous fluid producing fever		1720
Dessault, worms		1738
Rush, malignant fever		1798
Bosquillon, imagination		1809
Dr. Read, spinal marrow		1819

Having already shown, beyond all rational contradiction, that hydrophobia is certainly the result of a morbid poison introduced into the system of the animal which it affects, the *modus operandi* of the exciting cause, according to these various hypotheses, becomes much circumscribed. For example, if, with Mead and Rush, we consider hydrophobia as a fever, then must the inoculated virus be allowed to produce it after the manner in which the exanthematous viruses produce their respective febrile eruptions, or the different miasms, when inhaled, engender fevers. Of course we can make no allowance for Dr. Mead's perversion of the nervous fluid, as it is no longer believed to exist. But there is no more difficulty in comprehending how the rabious poison may produce its peculiar fever and spasms, than why the poison of small-pox produces a severe fever, often with convulsions and vomiting, and a severe inflammation of the muco-cutaneous membrane; or why the infection of pertussis produces a fever with peculiar spasmodic coughing, and a copious discharge from the mouth and fauces. Nor is there any more difficulty in comprehending these latter effects, than in conceiving why croton oil, introduced into the circulation by abrasion or puncture, excites violent action in the bowels; tartar emetic in the stomach; and squill in the kidneys. They are the simple result of that original quantity of irritability wherewith these parts have been furnished, and by which alone they become susceptible of the

influence of the given irritant applied in a certain dose.

Diversity of property, whether of organic or inorganic structures, is the great beauty of creation, and constitutes the essence of individual natures, or that character by which they are distinguished from every other thing, and are thus solely the things they are. It is the principle medium through which its divine architect conserves the actions of the machine, which in this sense, become just so many fulfilments of his original purpose. Such effects of external upon susceptible bodies differ in little from the action of an acid upon an alkali, being equally the result of special properties previously impressed upon each; and are facts not to be explained but observed. The blood of an animal imbued with the canine poison may have its power of irritation exactly in that degree of modification which produces most vehement effects upon the nerves of voluntary motion, and upon the distributions and connexions of the eighth pair; and yet not to be in a state capable of effecting the least impression upon the liver, spleen, kidneys, or uterus: and, on the other hand, the motor and pneumogastric series of the nervous system may be originally endowed with exactly such a degree of susceptibility as enables them to originate those high indications of excitement which they exhibit in hydrophobia, with frequent febrile reaction whenever the virus is applied to them through the medium of the blood. The peculiar effects of every individual virus hitherto discovered, prove that this mutual coaptation of the stimulus and sentient fibre to each other is not merely a vague supposition of what may be, but an actual induction supported by the analogy of every known example of inoculated virus. We repeat then, that this notion of the hydrophobic poison producing great nervous irritation and fever, from which all the other phenomena naturally result, is far from being wild and fanciful; and, independently of the names of its distinguished authors, merits due consideration. It has the advantage of embracing nearly all the phenomena, as it is not necessary that the fever should appear on any particular day, or appear at all, just as we see obtain in tetanus and whooping-cough; neither when it does come, does there seem much excuse for so keen a verbal critic as Dr. Rush terming it *malignant*. The vomiting, gastric pain, appearances on dissection, as well as the peculiar character of the matter ejected, the thirst and spasmodic irritation of the throat, and the necessity of some portion of the acrid saliva being received into the stomach, are circumstances which have induced many distinguished men to believe that the virus first exerts its malignant influence upon the stomach, and from this, as a centre, radiates its action to the most distant points of the system which have any consent with the stomach, by that sympathetic irritation which we see prevailing in so many gastric diseases. This view is also ingenious, and comprehends a great many of the phenomena of hydrophobia; but it appears liable to some fatal objections; it does not explain the total absence of gastric symptoms in

many individuals, and of traces of disease in the tunics of the stomach in many others; and there is frequently no rejection of solid food by hydrophobic patients, or of solids and fluids by dogs, as happens in gastritis, and might be expected to take place if the stomach was in any way the primary seat of hydrophobic irritation. The affection of the respiratory organs also, seems quite too violent to be an effect of mere gastric irritation.

Still less tenable was the ancient hypothesis, that the virus of the mad dog first acted upon the liver, producing a large secretion of black bile: that this black bile accumulating, frequently gave rise to the symptoms of melancholy and hypochondriasis, diseases which were then supposed to be produced by that fluid: that the black bile then made its way into the stomach and excited hydrophobia, very much in the same way we have just sketched. There is no black bile, and the occasional appearance of bile in the stomach is the effect of the vomiting, not the cause. The same series of objections apply to the opinion which refers the principal focus of hydrophobic action to simple inflammation of the pharynx and larynx, or of the two former, or of the latter alone; in all these situations the marks of inflammation are often entirely absent. The sensibility of the fauces, the copiousness of the salivary secretion, the thirst and suffocating spasm, bear no proportion whatever to the presence, absence, or degree of these traces of inflammation which scarcely ever appear at the commencement of the disease, and are therefore consecutive of some other and later part of it. Besides, the general sympathies of the fauces are not very extensive, and they are so ordinarily the seat of inflammation that it would not be rash to assert that no one case out of a million exhibits a regular specimen of hydrophobia, even in its non-rabid form; while scarcely one case in a hundred is without a regular display of them in the rabid form. This consideration mightily reduces the number of chances in favour of the phlegmasian hypothesis which counts many able supporters.

Authors have conjectured that the initial seat of the virus might probably be somewhere in the respiratory apparatus, in the larynx, bronchi, lungs, diaphragm, thoracic muscles, or all of them together. This conception has certainly the advantage of coinciding with appearances at a very early stage of the disease, in which frequent sighing, a panting motion of the chest, uneasy respiration, an occasional sense of suffocation and fainting, are generally experienced: it has the further advantage of explaining what takes place in the pharynx, gullet, and stomach much better than the assuming these symptoms to be primary; and elucidates the perverted state of respiration considered as their consequence. But the theory affords no rational explanation of the fever, the mental aberration, the salivation, the tremors, the spasms; and these objections seem fatal; for no theory of a disease can be admitted which leaves as much as it illustrates unexplained. We have said enough when we mention M. Dessault's

theory of organic worms; of which the day is long past.

It seems hardly necessary to observe, that those ancient authors of the Alexandrian school who ascribed the seat of the disease to the brain and its membranes, merely did so because they considered these organs as the primary origins of the nerves; the nerves of sense being conceived to proceed from the mass of the brain and spinal marrow, while the nerves of motion were believed to spring, by small roots, from the membranes that invest them. This is also the comment of Aurelianus, and we are warranted therefore in affirming that their theory of hydrophobia differed not essentially from that of Mead and Rush, and does not therefore require to be considered apart; since, like these authors, almost all the ancients admitted the absorption of a virus. Themison, Aurelianus, and others of the methodic sect, conceived that the virus inflamed and dried up the blood, thereby producing a deficiency of secretion into the fauces and gullet, great thirst, and a general constricted state of the system. In short it was a well-marked example of the *stricture*, and accordingly directed all their efforts to subdue this state of rigidity by introducing fluids into the colon, plunging the patients into water, and other contrivances. M. Majendie's method of injecting tepid water into the veins might be expected to answer the same purpose; but it is impossible to prove the existence of constriction in hydrophobia; thirst is not always present; and the whole theory has been long since exploded, as incompatible with the doctrine of the circulation and with the general principles of pathology.

Of late years, since the experiments of Legallois, Wilson Philip, and Majendie, respecting the structure, function, and relations of the spinal chord have become so justly celebrated, Dr. Reid of Dublin, and several continental writers have endeavoured to revive a part of the above ancient theory, and to replace the principal seat of hydrophobia in the spinal marrow. Some slight dilatation in the vessels of this part, and vestiges of inflammation noted in one or two dissections, seem to be the only new facts upon which, in connexion with the light thrown upon the spinal portion of the nervous system by those experimentalists, this idea is at present supported. But it leaves the mental phenomena, the salivation, the spasms of the face, the tenderness and unnatural appearance of the skin, the gastric, and particularly the diaphragmatic irritation, altogether unexplained; for it is scarcely necessary to observe that the nerves of the stomach and diaphragm originate much above the points where such congestions are observed; and which, though they be often totally absent, are not therefore to be totally denied, since both men and animals (Gillman's pigs for example) often exhibit a distinct paraplegia some time before death. It is not improbable that the paraplegia here alluded to in man is that which has given rise to the numerous fables of the older authors, of hydrophobic patients rolling themselves up like a ball, crawling on all-fours, and attempting to

lap water in the horizontal posture, like a dog, &c. "In a state of despondency," says Dr. White, of Bury St. Edmunds, "and with agonising groans, the patient threw himself down, as we thought, in a corner of the room, and soon after crawled about in a restless manner, dragging his legs after him, which proved to us that he fell on the floor from his lower limbs being palsied."

Amidst so many ingenious hypotheses, if we are finally asked which of the number appears to us to be on the whole the most consonant to reason, we at present say that an explanation of the phenomena which does little violence to the recognized principles of pathology may most easily be drawn from the first, which assumes that the imbibed virus, like most other poisons, mainly and initiatively spends its force upon the nervous system. It is a well-known fact that all severe injuries inflicted upon this system, whether in the way of stimulus or depression, manifest the gravity of their influence most remarkably in that series of organs supplied by the eighth pair: and conversely, experimentalists, as M. Desmoulins, have found that the smallest pressure even of a drop of blood upon the origin of this nerve in animals almost instantly extinguishes life. The affection, then, so strongly marked, of the parts supplied by this nerve in hydrophobia, and the curious circumstance of its never extending its ravages below its pneumo-gastric termination, may perhaps be considered merely as an index of the deadly virulence of the cause. Still we have shown above that there is no difficulty in comprehending, with the ancient Gaius, that the poison of rabies exerts a peculiar inveteracy of action upon the origin of the respiratory column and the commencement of the eighth pair, just as the vomiting, dysphagia, and laborious respiration, occurring from a violent blow on the head, may either be assumed as the known ultimate effect of general compression, or as a modification of these by some special injury at the same time inflicted on the origin of the same pair.

Diagnosis.—Properly speaking, there is scarcely any disease that a careful practitioner would confound with hydrophobia; but in cases where no rabid impregnation is suspected, the disease may be mistaken for phrenitis, mania, fever, or tetanus; and, in the incipient stages, for melancholy, hypochondriasis, and hysteria. It can only be mistaken for any one of the three latter during a few hours from the commencement. Hysteria and hypochondriasis advance by slow degrees, and rarely have fever, difficulty of respiration, tenderness of skin, or salivation. Melancholy is altogether a chronic disease, and never has convulsions, spasms of the throat, dread of water, difficult respiration, and vomiting among its symptoms. It is true that phrenitis, and what was long classed as a form of it, delirium tremens, have tremors, suspicious fears, tenderness of skin, convulsions and difficult swallowing; but there is no affection of the stomach or respiratory system, no vomiting, no salivation: nay, spasmodic difficulty of swallowing occurs not in one case out of a hundred.

From mania it is distinguished as soon as the spasms, difficulty of swallowing, and salivation appear. Indeed the mental aberration, the aversion to certain objects, and the fever which is occasionally present in both, seem to be almost the only points of resemblance. Dr. Rush has entered into a long argument in order to evince the identity of fever and hydrophobia; but though hydrophobia has fever, it does not follow that hydrophobia is the same thing as fever; or, in other words, is fever alone. In short, we have often repeated that in many cases of hydrophobia fever actually supervenes; and that where it does occur, it is seldom a primary symptom. The distinction of hydrophobia from tetanus has been made the subject of much discussion. The two diseases seem first to have been compared with each other by Democritus; but it cannot now be known whether he, or indeed any of the ancients, considered the apparently tetanic phenomena of hydrophobia to arise from the wound alone. On the contrary, they seem almost all to have admitted the existence of a virus; and from the earliest periods to have attempted to account for the symptoms by the operation of this poison upon some peculiar series of organs, from the excitement of which they conceived all the visible symptoms to proceed. Democritus traced it to the tendons or muscles; the followers of Herophilus and Erasistratus, the great discoverers of the functions of the nerves, naturally referred the virus to that system; Asclepiades traced it to the stomach; the methodists to their favourite *strictum*, &c. But none who admitted the reality of the disease appear to have disputed the existence of the virus.

Dr. Mease, of Philadelphia, in 1793, published an able work on hydrophobia, in which he contended for the uncertainty of the virus, and makes out hydrophobia to be purely a nervous affection. Charles Bader, in a dissertation on hydrophobia, published 1792, maintains that there is much less of contagious character in hydrophobia than is generally believed, and draws a formal parallel between tetanus and hydrophobia. The non-rabid form of hydrophobia is occasionally symptomatic of tetanus; and both tetanus and hydrophobia seem to originate most readily from a small punctured or lacerated wound. Both exhibit paroxysms of universal convulsion, and occasionally fever, and both carry off a great majority of patients before the sixth day. These are the chief circumstances in which the two diseases agree; and to appeal to more minute but very uncertain points of correspondence, as has been done by the writers who contend with such zeal for their identity, would add nothing to the justness of the comparison. But we have already shown, when discussing the questions respecting the *modus operandi* of the cause of hydrophobia, that there intervene many undeniable discrepancies between the two diseases; and to these many others must be added. Tetanus, as its name implies, consists essentially in a *tonic* spasm, generally

occupying the muscles of the lower jaw, of the neck, of the spine, and the limbs; of the thorax, abdomen, and diaphragm; and always observed more to affect the extensors than the flexors. These contractions of the muscles are occasionally relieved by intervals of ease, but never by entire relaxation; nay, in successful cases, Dr. Currie assures us the deep indentations made in the face by the terrible contractions of its muscles are visible afterwards for many years, and imprint on the countenance a severer character than it previously possessed. A stiff immovable state of the lower jaw, scarcely to be overcome by any ordinary force, is present during almost the whole of nearly every case of tetanus, and has acquired, for that variety of the disease in which the muscles of the spine are little extended, the name of *trismus*, or lock-jaw. On the contrary, the spasms of hydrophobia are always *clonic*, that is to say, they are always of brief duration, and are succeeded by a period of complete relaxation, generally of many hours' duration in the beginning of the disease, unless provoked by attempts to make the patient swallow; and even at the last fatal paroxysm, tonic spasm, and particularly locked jaw, are very seldom to be observed. A discharge of saliva is an exceedingly rare occurrence in tetanus; in hydrophobia it is a general and characteristic symptom. Thirst is rare in tetanus; it is characteristic of hydrophobia. Vomiting and gastric pain or uneasiness scarcely ever occur in tetanus; they are so general in hydrophobia as to be mistaken by many for the essential circumstances of the disease. It is only in rare forms of tetanus that attempts to drink bring on guttural spasm, a dread of fluids, and their violent rejection when introduced; but in hydrophobia this is the pathognomonic triad which fixes the character of every case, with a very few unimportant exceptions. In tetanus, the mind is almost always clear to the last; in hydrophobia, almost from the beginning, numberless deviations from the usual habits of thought and action indicate an incipient stage of mental aberration, which often passes on to delirium or raging madness. In tetanus, fever is rarely present; in hydrophobia, it is frequently present. From tetanus, many recover; from hydrophobia, none recover. Tetanus takes its rise from cold or from any sort of wound; hydrophobia from the bite of a rabid animal. Tetanus, though the usual result of small punctured and lacerated wounds, rarely follows from the bite of a rabid animal; hydrophobia with much greater frequency in proportion to the number of persons bitten, it is said so much as one out of every twenty-five. Tetanus seems more frequent in warm climates; hydrophobia in cold climates, or at least indifferently. Tetanus seems to occur almost any time after the injury; hydrophobia chiefly from the thirtieth to the sixtieth day. It has never been contended that the bite of a tetanic animal communicates tetanus; but it is acknowledged that the bite of a hydrophobic animal communicates hydrophobia. The countenance of a tetanic patient bears no resemblance to the

physiognomy of hydrophobia: in the former, the eye is natural, and the general aspect is that of suffering; in the latter, the eye is preternaturally bright and glistening, the face occasionally exhibiting frightful convulsions, and the pain of the diaphragm is not characterized by a constant sense of the sternum being dragged towards the spine, as is the case in tetanus; while tetanus, on the other hand, scarcely ever exhibits that laborious panting respiration, that tremor of the whole muscles, and that intolerant sensibility of the surface and of the organs of sense, which distinguish hydrophobia. Indeed it is perhaps only by reasoning upon the uncommon as if it were the ordinary case that any person, although exposed to the illusion of his own ideas in the retirement of his closet, could mistake the one disease for the other.

Morbid anatomy.—Whoever peruses with care and attention the various dissections of hydrophobic patients which have at different times been published, will be obliged, however reluctantly, to admit that the pathology of rabies canina is still involved in considerable obscurity, and that no distinctive pathological character of the disease has as yet been satisfactorily determined. The brain has been examined with much care and attention. In some instances the dura mater has been found to have assumed a darker hue than usual. The capillaries of the tunica arachnoidea and pia mater have also been met with minutely injected with blood. This state of these membranes occurred in the dissection of a case published by Dr. Marshall, as well as in several others on record. Trollet has noticed the gorged condition and dark colour of the plexus choroides. Effusion of serum has been observed between the dura mater and tunica arachnoidea; between the latter membrane and the pia mater; between the pia mater and brain; and also in the ventricles. The substance of the brain itself has been detected in a harder state than natural in one or two instances; in others, it has been found to have undergone a certain degree of "*ramolissement*." Both Bonetus and Lieutaud, however, have alluded to cases in which this organ presented no marks of disease.

Inflammation of the *pharynx* and *œsophagus* has been noticed in several dissections of hydrophobic patients; but cases are on record in which no inflammatory appearance in these parts has been observed. On examination of a patient of Dr. Rutherford's, who died of rabies canina, Dr. Monro was unable to detect any morbid alteration, either in the pharynx, œsophagus, larynx, stomach, or intestines. In one instance it will be shown that we have met with an abrasion of the internal membrane of the œsophagus. In a fatal case of this disease, too, related by Dr. Ferriar, a morbid appearance presented itself in the lower part of the œsophagus. About two inches above the cardia, the epidermis of the œsophagus was abraded in irregular points, and exposed an inflamed surface of a dark red colour; still lower, the abrasion became linear and extended into

the stomach itself. The edges of the epidermis surrounding the abrasions were unequal and elevated. A similar affection was traced along the lesser curvature of the stomach, but growing fainter in its progress to the pylorus, where it was least discernible, and about which it seemed to terminate. The whole of the inflamed parts bore a striated appearance resembling the effect of corrosion, darkest in the œsophagus, and lighter and more indistinct towards the pylorus. In two cases mentioned by Dr. Vaughan no inflammation of the œsophagus appeared on dissection. The *internal coat of the stomach* has been discovered in a highly inflammatory state in not a few instances of rabies; and dark purple-like suffusions have also been observed upon it. This organ has also been found to contain a smaller or greater quantity of coloured matter. It has been supposed that this inflammatory condition of the mucous membrane of the pharynx, œsophagus, and stomach, satisfactorily accounts for the sense of suffocation, extreme thirst, morbid antipathy to liquids, and burning heat along the whole œsophageal tube, mostly experienced by the hydrophobic patient; but it must be recollected that such a state of these parts is by no means constantly present, as is proved from the cases related by Dr. Hamilton and other writers; and hence it is not essential to the existence of the disease. From the examinations of M. Trollet, it appears that the mucous membrane of the *trachea and bronchi* afforded evidence of inflammatory action, and was covered over with a considerable quantity of frothy mucus; and the membranes of the brain, particularly the pia mater, exhibited marks of great vascularity. The frothy matter he supposed to be the product of the inflamed mucous membrane. "*La bave écumeuse des hydrophobes,*" he observes, "*est un produit de la membrane muqueuse enflammée, puisque nous l'avons toujours vue dans les parties des voies aëriennes où cette membrane étoit vivement colorée, et qui étoient le siège de la douleur. Elle est chassée sur les lèvres de l'hydrophobe dans la dernière période de la maladie, comme le mucus altéré dans l'agonie d'une personne affectée de phthisie ou de catarrhe, lorsque la respiration est stertoreuse et laborieuse.*" Lalouette has also noticed this peculiar frothy matter in the trachea and bronchi:—"Une humeur," he remarks, "que l'on peut comparer à une salive écumeuse qui enduit toute l'arrière bouche ainsi que le larynx, le pharynx, la trachée artère, et les grosses divisions des bronches. Elle se trouve en plus ou moins grande quantité chez les différents sujets." That the lining membrane of the trachea and bronchi is sometimes in a state of inflammation cannot be denied, but we are satisfied that Trollet's view of the pathology of rabies is too limited; for it will be found, upon a comparative examination of the number of dissections of hydrophobic persons on record, that the stomach has been more frequently met with in a morbid condition than the trachea, bronchi, or any other part of the body. The *salivary glands* have occasionally been observed

of increased size and vascularity. In some instances there has been inflammation of the pulmonary tissue, but more frequently great venous congestion.

Dr. Ferriar was almost disposed to consider the disease as dependent on obstruction of the pulmonary circulation, but his conjecture has not been supported by subsequent pathological investigation. The *pleura* have been noticed in a thickened and inflamed state; and we meet with fatal cases of hydrophobia in some of the earlier medical records, in which *various derangements of the heart, pericardium, liver, spleen, and mesentery* are described; but it is impossible to peruse these dissections without being convinced that the morbid changes enumerated are merely accidental, and the result of other causes than the virus of rabies. Some pathologists of eminence, amongst whom may be mentioned the names of Salin, Brera, Sanders, and Reid, supposed that they had satisfactorily proved that the symptoms of hydrophobia proceeded from a morbid condition of the *spinal marrow*; but it may be correctly stated that their opinions have not been confirmed by the general experience of the profession. In some examples of this disease, (as in the two which we shall notice,) unequivocal marks of vascularity of the membranes of the spinal chord have been present, but, generally speaking, not the least vestiges of inflammatory action either in the medulla spinalis or its investing tunics have been discovered. In one instance, related by Mr. F. Godrich, the whole chord was considerably inflamed; and opposite the two last cervical and dorsal vertebræ the cellular substance was studded with dark patches of coagulated blood, the theca vertebralis thickened, and the chord in an active state of inflammation. The larynx and pharynx bore not the slightest vestige of disease. We may, however, venture to assert that no such connexion as that of cause and effect exists between an inflammatory state of the spine and the phenomena of hydrophobia; for it is well known that effusion of serum into the theca vertebralis, and other signs of increased vascular action in the spine, have been frequently met with in diseases very different from the one under consideration.

As dissections of hydrophobic patients are by no means frequent, it may be instructive briefly to detail the *chief* morbid appearances detected in *five fatal cases* of this disease which have come under our own observation. In one, where the patient died in seven days from the period of his first experiencing pain in the bitten part, and in fifty-six hours from the commencement of the hydrophobic symptoms, the following morbid alterations were observed:—*Brain*.—Vessels of the dura mater preternaturally distended with blood, the vessels ramifying in a distinct manner. Pia mater somewhat distended, and a larger quantity of blood interposed between the membranes than usual. Left ventricle with the usual quantity of fluid. The substance of the brain of the usual consistence.

When pared off in slices, the surfaces showed numerous brown spots. The vessels of the basis, or cerebellum, were more than usually turgid, and somewhat more of fluid effused than usual. *Pharynx* and *larynx*.—No appearance of inflammation. *Thorax*.—Lungs perfectly sound. Heart flaccid. No coagulum in its cavities; two ounces of fluid within the pericardium. *Œsophagus*.—Upon opening the œsophagus, a substance was found lying closely within the orifice without filling up the cavity. This membrane was nearly the length of the œsophagus; when inflated with the blow-pipe it assumed a tubular appearance. The abrasion of the internal membrane seemed to extend as far as this substance. The external membrane of a deep red colour. The whole internal surface dotted with purple-like suffusions. *Stomach*.—Contents about one pint, the external membrane of a deep red colour. Its inside covered with broad dark purple-like suffusions, especially about the cardiac orifice. The intestines sound; the liver of the usual healthy character; appearance of bladder natural. The same marks of disease usually exist in most cases of hydrophobia after death, with the exception of the remarkable membrane found in the œsophagus of the one now described, which was considered by all present a portion of the internal membrane of the œsophagus. In *another* instance, on opening the head, the sinuses were found gorged with blood, and the vessels of the arachnoid and pia mater exhibited marks of highly increased vascular action. The lateral ventricles contained a small quantity of serous fluid, and the plexus choroides was of a pale colour. The substance of the brain was softer than natural. The vessels of the spinal arachnoid and pia mater were minutely injected. The lungs and the bronchial mucous membrane were perfectly healthy. The heart and its large vessels were also sound. The lining membrane of the pharynx and œsophagus was somewhat redder than usual. The stomach presented some few slight ecchymoses; the intestines were free from disease. In a *third* case in which the body was carefully examined by a very distinguished anatomical teacher, Mr. Turner, there was considerable vascularity of the pia mater, with slight serous effusion in the lateral ventricles. The substance of the brain was of a firm consistence. Strong adhesions existed between the costal and pulmonary pleura in both cavities of the chest. The lungs were in a state of great congestion, and when cut into, a considerable quantity of bloody fluid flowed from their substance. The membrane of the trachea and the larger bronchial ramifications were here and there marked with dark purple-like suffusions, and had assumed throughout a darker hue than usual. On an inspection of the inside of the fauces, pharynx, and œsophagus, a scarlet uniform redness was observable. The heart was sound. The stomach exhibited evident marks of congestion, if not of inflammation. Numerous small dark-coloured spots appeared about the

superior orifice, and might be traced along the larger curvature of the organ. These spots very much resembled the marks of small shot. All the other viscera of the abdomen, with the exception of the liver, which was slightly indurated, afforded no marks of disease. The pia mater tunic of the spine, like that of the brain, was much more vascular than natural. The *fourth* instance was that of a boy, nine years of age, who was bitten by a mad dog about three months previously to the occurrence of the symptoms of the disease. He was under the care of a highly respectable surgeon, Mr. Brownbill, of Salford, to whom we were indebted for an opportunity of attending the inspection. The patient died in sixteen hours after the malady had fairly developed itself. Within the cranium nothing unusual could be detected, except a slight turgescence of the vessels of the pia mater, and rather more distention of the choroid plexus than usual. The fauces, œsophagus, and parts adjacent were in a natural state, but the effects of inflammation were very evident upon the lining membrane of the trachea and the larger bronchial tubes. The lungs were sound, but somewhat distended with blood. The stomach contained a small quantity of brownish fluid, but no diseased appearances were detected in it. The other abdominal viscera exhibited nothing peculiar. The spinal marrow was inspected with much care, but there were no marks of inflammation either in its membranes or substance. In the *fifth* and last case we have witnessed, where death occurred in thirty-four hours after the first unequivocal symptoms of the disease had been present, the following were the appearances on dissection. The brain was in a natural state. The fauces and lower part of the œsophagus afforded slight signs of inflammation; the vessels on the inner coat of the stomach were much more distinctly marked than usual; and a few spots of extravasated blood were observable along the cardiac extremity of the organ. The other abdominal viscera were sound. Nothing unusual presented itself either in the trachea or bronchi. The lungs were somewhat turgid with blood. The spine was free from disease.

All the attention we have been able to pay to the anatomical character of rabies canina leads us to agree with Dr. James Johnson in the following remarks: "That it cannot be denied, but that the most evident indications of inflammatory action attend the symptoms, and distinguish the pathology of hydrophobia; that we have often inflammation of the œsophagus, pharynx, and larynx, and occasionally of the brain and spinal chord; yet it is generally admitted that these appearances are more the consequences than the cause of the disorder, and that although frequently present with, they are by no means essential to the existence of hydrophobic action." That they are not *essential* to the existence of the disease is proved by the fact that, in several cases on record, in which the post mortem examinations

have been made by eminent and experienced pathologists, no morbid appearances have been detected in any organ or tissue of the body. Some of the morbid appearances noticed above are no doubt produced by the violence of the convulsive motions which invariably accompany the disease. Lalouette, an able French writer on rabies, has remarked, "*L'ouverture de plusieurs cadavres de personnes mortes à la suite de la rage, ne m'a présenté aucun phénomène particulier à cette maladie. On ne trouve nulle part aucun signe de phlogose sanguine, ni d'inflammation. Je n'ai observé nulle part aucun signe de dissolution, aucun engorgement ou phlogose humorale; aucune gangrène interne, ni même aucune apparence de disposition à cette diathèse.*"

Treatment of Hydrophobia.—The reader will in all probability be prepared, from a perusal of the preceding account of the *pathology* of hydrophobia, to anticipate the conclusion that in a disease on whose nature anatomical investigation throws such feeble light, the treatment must necessarily be unsettled, and in a great measure conjectural. Dr. Good correctly observed, that the mode of cure in this affection is a field still perfectly open for trial; for, at this moment, we have no specific remedy, nor any plan that can be depended upon, after the disease shows itself. There is, perhaps, no malady to which mankind is liable, that has called forth such a host of remedies for its removal, and alike defied their single and united powers. The long list of the *materia medica* has been ransacked to discover some one article capable of arresting the progress of this disease, but all have hitherto proved inert. It would be absurd to do more than simply name several of the substances to which ignorance and superstition have attached importance in the treatment of hydrophobia. Amongst these may be classed the celebrated pulvis antilyssus, the theriacas, the alysmaplantago, the rhus coriaria, the scutellaria, the genista, the Ormskirk medicine, and the tonquin powder. Each of the above remedies has had the title of a specific attached to it, and enjoyed for a time unmerited reputation. In the consideration of the treatment of hydrophobia, it appears to us proper to notice, first, the *prophylactic measures* which are indicated; and, next, the *means to be employed after the disease has been once developed*.

It is fortunate that the community at large are now more strongly convinced than formerly of the extreme folly as well as danger of resorting to the use of the several vaunted specifics for the prevention of hydrophobia, and thus delaying application to the well informed and regularly educated practitioner on the immediate occurrence of the bite. It cannot be too strongly impressed upon the minds of the public, that not a moment is to be lost in soliciting judicious medical aid after the bite of a rabid animal, for the longer the delay the greater the danger of the virus entering the system and producing the disease. We shall endeavour to point out the prophylactic plan

which seems to afford the surest ground for a proper confidence and security against future mischief. The wound should be well and perseveringly washed from the earliest moment of its infliction. The patient may himself adopt this simple practice until surgical aid be obtained. Dr. Haygarth has suggested that the ablution of the wound may be well effected by directing upon it a continued stream of water from the spout of a tea-kettle, held up at a considerable distance. "If the canine poison," he observes, "infused into a wound were of a peculiar colour, as black, like ink, we should all be aware that plenty of water and patient diligence would effectually wash out the dark dye, but this could not be effected by a slight and superficial ablution." After the bitten part has been well and thoroughly washed, it then becomes a question what further means should be employed to prevent absorption of the virus. Upon this point, it will be found that scarcely any two practitioners are agreed; some giving the preference to *excision*, and others to the *actual* or *potential* cautery. The use of the *actual* cautery has been chiefly recommended by some of the earlier writers, and is a practice but seldom adopted in the present day, though it is by no means destitute of advantage under particular circumstances. The application of caustics *alone* to the wound has been relied upon by some eminent practitioners. Mr. Youatt, who may perhaps justly be considered the first living authority on canine madness, has warmly advocated the use of the caustic. He recommends the nitrate of silver. Troillet prefers the hydrochlorate of antimony. Earle, in his evidence given before a Committee of the House of Commons in 1830, says, that he does not place much reliance on any caustic, except strong nitric acid, for it acts very deeply, whereas "other caustic, for instance, caustic potash, when there is any wound, becomes decomposed by the blood, and does not penetrate to the depth that nitric acid does; and nitric acid forms a dry eschar." Other surgeons, on the contrary, strongly advise the employment of the potassa fusa. Mr. Youatt considers the lunar caustic perfectly manageable, and, when sharpened to a point, as capable of being applied with certainty to every recess and sinuosity of the wound. "The potash and the nitric acid," he observes, "will destroy the substances with which they come in contact, but the combination of the caustic and the animal fibre will be a soft or semi-fluid mass. In this the virus is suspended, and with this it lies upon and remains in intimate contact with the living fibre beneath. Then there is danger of re-inoculation; and it would seem that this fatal process is often accomplished. The eschar formed by the nitrate of silver is hard, dry, and insoluble. If the whole of the wound has been exposed to its action, an insoluble compound of animal fibre and the metallic salt is produced, in which the virus is wrapped up, and from which it cannot be separated. In a short time the dead matter sloughs off, and the virus is thrown

off with it." Mr. Youatt informs us that he has been bitten four times by dogs decidedly rabid, and at each time he freely applied the caustic to the wound; and he has remained free from the complaint. He has also operated on more than four hundred persons of whose disease there could be no question, and has not lost a patient. His experience is opposed to the practice of keeping the wound open for several weeks after the application of the caustic, for he supposes, that if a minute portion of the virus should perchance remain in the wound, by applying stimulating ingredients to the part there is considerable risk of exciting the absorbents to action, and producing that disease which would not otherwise have had existence. "Destroy the part at once by the knife or the caustic," he observes, "and then adopt the mildest means speedily to heal the wound." The testimony of Mr. Youatt in favour of caustic is unquestionably very weighty, and entitled to the utmost consideration; but still the fact cannot be concealed, that in the hands of other practitioners, the results of the use of the caustic have not been equally favourable. In the case of Rowley, noticed by Dr. Hamilton, caustic was very carefully applied to the wound by Mr. John Hunter shortly after the infliction of the bite; still the hydrophobic symptoms appeared, and the youth died. It would not be difficult to multiply the cases of failure after a fair trial of the caustic. Mr. Youatt allows that every surgeon must decide for himself respecting the comparative value of caustic and the knife, but he requests that those who prefer the caustic may be no longer exposed to so much gratuitous abuse. He does not condemn the use of the scalpel, but gives a decided preference to the caustic, and only employs the knife in order fairly to get at the wound. It appears, however, from the facts already before the public, that the general experience of the profession is in favour of an *immediate excision* of the bitten part, as affording the best security from danger. Some practitioners have strongly recommended the conjoint use of excision and the caustic.

We shall now briefly give our opinion of the best and most certain means of preventing the disease. It appears to us that *complete excision* of the bitten parts, when at all practicable, ought to be adopted without a moment's unnecessary delay for the trial of caustic or any other external irritant; for it is but seldom that any bad effects ensue from the bite, when this simple operation is carefully and effectually accomplished, and we really consider the medical man who omits this practice guilty of unpardonable neglect towards the unfortunate being who may be doomed, from his want of energy, to writhe under the agonies of this most horrible malady. Indeed the excision of the wounded part should always be employed even in cases where the animal is only supposed to be rabid; for though some degree of momentary pain may be occasioned by the knife, this is of trifling consequence when compared with the mental tranquillity which must result

from the conviction of a perfect immunity from the disease by the operation. The force of the above remarks will be felt, when it is considered that canine madness is *incurable*, according to the present state of our knowledge; for we are satisfied, from careful and extensive research on the subject, that when the symptoms of this disease have been once fairly developed, notwithstanding the most vigorous and diligent attempts of medical men to remove them, no cure has ever yet been effected, but the unhappy sufferer has had to struggle with torments such as the imagination cannot conceive, and which must be witnessed in order to be believed. This is a melancholy truth for mankind to know. When excision has been neglected on the first infliction of the wound, still we consider it highly proper that it should be performed at even a distant period from the bite; for it seems to be an established fact that the virus of a rabid animal does not, like other morbid poisons, such as small-pox, cow-pox, syphilis, and plague, always produce its effects within a limited time. Dr. Todd Thomson has expressed his opinion that the hydrophobic virus is not regulated by the usual laws of morbid poisons, and on that account he is inclined to believe that it remains in the bitten part, and the individual is safe till the habit becomes predisposed to the action of the poison, so that the part may be advantageously excised in the intervening time. A case is related by Professor Rust where the wound was excised thirty-one days after the bite, and after the hydrophobic symptoms had appeared, and still the patient's life was saved. When the wound is so situated that the whole of the bitten parts cannot be completely removed, then of course we must trust to the application of caustic, to scarification, or the actual cautery. Under these circumstances it is of the highest importance that the caustic be carefully and effectually used, for the safety of the patient in a great measure depends upon the manner in which this operation is in the first instance performed.

In order to ensure the removal of every part with which the dog's teeth may have come in contact, (for the smallest portion left may produce the disease,) it is necessary accurately to ascertain the depth of the wound, and the direction in which the teeth have penetrated. Unless the excision be carried beyond the bite, the operation fails to afford the patient a security from future danger. The surgeon cannot use too much care in removing the bitten part. We are informed that in one case Mr. Hunter removed the parts, as he thought, freely, and there was nothing on the under surface of the piece cut out that led him to suppose that he had not gone beyond the bite. But on examining the surface of the wound, he found a part in the middle which was hollow underneath, which showed he had not gone deep enough, but had left a ridge as it were over part of the passage made by the dog's teeth, and which could only have been discovered by examination after the operation.* Though we

have strongly recommended that the wounded part be cut out whenever it can be done with safety, still we see no objection to the application of caustic afterwards to the excised surface, as affording additional security from the greater probability of every particle of the virus being removed or destroyed. With proper deference to the experience of Mr. Youatt, as given above, respecting the impropriety of keeping the wound in a state of suppuration, we must observe that the facts stated on eminent German authority in favor of the practice seem to be incontrovertible. Dr. Wendt states that from the year 1810 to 1824 one hundred and eighty-four persons bitten by dogs were admitted into the Breslau hospital; of whom half were bitten by dogs absolutely mad, or supposed to be mad, and from the whole two only died. It is true, that besides keeping up a copious discharge from the wound for six weeks or longer, mercury was employed internally so as to induce salivation; still by far the greatest stress was placed on the external treatment. It is also mentioned in a very able review of several German essays on hydrophobia,* that at Zurich "the treatment consists of deep scarifications of the wound, the besmearing it with pulvis lyttæ, the application of a blister to the part, the keeping up a discharge from the wound and the blister during six weeks, and the rubbing-in of mercurial ointment till symptoms of approaching salivation come on; internally belladonna or calomel are given." In the same journal an account is given of the treatment pursued by T. M. Axter, senior surgeon of the large hospital at Vienna; and that of Dr. Hausbrand, district physician at Braunsberg, in cases of bites from animals. During twenty-seven years, Mr. Axter states that not a single old patient was ever brought back to the hospital with hydrophobia. Besides using internally, during three or six successive days, a grain of pulvis lyttæ with six grains of *canc. ocul.* and sugar, he applied externally over the wound a blister, and dressed it with the pulvis lyttæ or some stimulating lotion during the space of six weeks. Dr. Hausbrand first employed active bleeding in the earliest stage of the disease, then made deep scarifications of the wound, encouraged the flow of blood, washed the wound with salt and water, applied an ointment composed of unguentum basilicum and powdered cantharides, and kept up the suppuration during the space of three months at least. Internally, he directed the patient to take for three evenings a powder with camphor and opium, to drink elder tea, and keep up a copious perspiration. Eleven persons bitten by dogs actually mad, treated in this manner, remained perfectly free from the disease. We have noticed these four prophylactic modes of treatment chiefly with the view of shewing the nature and efficacy of the *local* means employed, and the evidence in support of the practice of continuing a discharge from the wound during several weeks. It must be recollected, however, that caution is necessary in

* Dr. Hunter, Transactions of a Medical Society.

* Ed. Med. and Surg. Journal, 1825.

drawing a positive conclusion in favor of any particular prophylactic measure, as the disease is by no means a necessary consequence of the bite; for it is a fact founded on the observation of a considerable number of cases, that upon the average not more than one person out of twenty-five who have been certainly exposed to the bite of a mad dog has become infected with the disease.

In noticing the inefficacy of the Ormskirk medicine, pulvis antilyssus, tonquin remedy, &c., Dr. Hunter says the question may be here asked, admitting the frequent failure of these remedies, have they not sometimes prevented the disease? The answer would certainly be in the affirmative if every person bitten by a mad dog who did not use some means of prevention were seized with the disease. But this is not the case, for in the human species the proportion of those bitten who are seized with hydrophobia is much less than of those who escape, even where no means of prevention are employed; we can, therefore, infer nothing in favour of these prophylactics, because they have been given in cases in which no hydrophobia has supervened.*

The application of a tight ligature to the affected part, at a short distance above the laceration, is strenuously recommended by Dr. Good from the first, even before the process of ablation, and the measure is sanctioned by the authority of Ambrose Paré, Trollet, and other eminent writers. "Analogy," says Dr. Good, "is altogether in favor of this operation, for it is well known to be one of the most important steps we can take in confining the poisonous effects of the rattlesnake and other venomous animals, and of mitigating its violence by the torpor which follows." We have had no experience of the beneficial effect of the ligature after bites from rabid animals, but we see no objection to the adoption of the practice. Cupping-glasses have also been applied to the wound. Celsus even recommended them.† More recently, the cupping-glass has been strongly advised by Dr. Barry, who has performed a variety of ingenious experiments relative to the absorption of several vegetable, mineral, and reptile poisons. It has been his aim to prove that absorption cannot take place in vacuo, and certainly the results of his experiments seem to us satisfactorily to establish the fact. We conceive that the cupping-glass is likely to prove a highly efficacious remedy in cases of wounds inflicted by poisonous or rabid animals, and we strongly recommend its early and diligent application *after* a careful excision of the injured part; for it by no means supersedes the use of the knife. Mr. Youatt rather objects to the cupping-glass, for he expresses a fear lest the virus, forced from the texture with which it lies in contact by the rush of blood from the substance beneath, may inoculate or become entangled with the parts of the wound; still he thinks that it may be useful after excision of the part, but as connected

with the caustic, that it can be of no avail. Amputation has been deemed advisable by some surgeons when the bite has been situated in a part, as in one of the fingers, to which a cupping-glass could not be effectually applied; or when a limb has been bitten in many places, or very deeply in parts not admitting of excision, as through the tarsus or carpus. Mr. Samuel Cooper thinks that under these circumstances immediate amputation might be warrantable *before* the accession of the symptoms. He has noticed a case that occurred at Guy's Hospital some time ago, in which a limb was amputated after the symptoms of hydrophobia had appeared, but without the least check being put to the complaint. "The performance of amputation," this able surgeon justly observes, "previously to the commencement of the symptoms, is a very different practice from that of amputating parts after the symptoms have begun."*

It may be proper here to allude to the plan proposed by Dr. Marochetti for preventing the development of hydrophobia. He believes that the hydrophobic poison, after remaining a short period in the wound, fixes itself for a certain time under the tongue, at each side of the frænum, where one or two little tumours or vesicles appear, in which may be perceived with a probe a fluctuating liquid. Dr. Marochetti states that the usual time of the appearance of these small knots is within the third and ninth day after the bite, and that if they are not opened within the first twenty-four hours after their formation, the poison is re-absorbed into the system, and all hopes of the patient's recovery are banished. He, therefore, strongly recommends that such persons as have the misfortune to receive a bite from a rabid animal should be examined under the tongue immediately, and that attention should be paid to this part during six weeks; for if these vesicles do not appear in this time, he considers the patient to be perfectly secure from future danger. When, however, they are detected, he directs that they should be instantly opened with a lancet, and then cauterized with a red-hot needle; and that the patient should gargle assiduously with a decoction of broom, and take daily one pound and a half of the infusion of the tops of the same plant, or four drachms of the powder. Professor Rossi has also published a case in the *Annali Universali*, in which a cure of hydrophobia is said to have been effected by taking a glassful of vinegar, and the *genista lutea tinctoria* internally, and by having the sublingual glands cauterized three successive times. In the examples of hydrophobia which have fallen under our own observation and that of some other practitioners, the knots or vesicles under the tongue, described by Dr. Marochetti, have been looked for in vain; and, indeed, their supposed presence seems to be a mere anatomical delusion. It may be correctly said that Marochetti's statements have not been confirmed by the general experience of the profession, so that practitioners may be undeceived

* Good's Study of Medicine, last edition.

in any expectations of security they might be induced to form from adopting his process to the neglect of the means noticed above; for the results of such misplaced confidence would be irremediable. We venture to repeat our conviction of the imperative necessity, in every case of injury from a rabid animal, of deeply and effectually cutting out the bitten part when it can be done with perfect safety, and of the propriety of keeping up a free discharge from the wound for several weeks by the aid of some active external irritant; and that when the operation of excision is inadmissible, recourse must be had to scarification, lunar caustic, or the actual cautery.

Amongst the chief preservative means that have been employed *internally* in conjunction with the local plan of cure, we may merely mention belladonna, cantharides, mercurials, emetics, volatile alkali, broom decoction, and chlorine; for it would be a waste of the reader's time to present him with a detailed examination of the individual efficacy of these several remedies as preventives of the fatal consequences of the bites of rabid animals, since the most ample experience has proved them to be altogether unavailing, and therefore undeserving of future confidence. To the vaunted specifics before named no further allusion is necessary.

Having thus considered the *prophylactic measures* which are indicated, we may next notice the means to be employed *after the disease has been once developed*.

This part of our inquiry is attended with some degree of difficulty, because no successful method of cure has as yet been discovered, after the characteristic symptoms of hydrophobia have once appeared. "There is, indeed, no disease," as Dr. Good justly remarks, "for which so many remedies have been devised, and none in which the mortifying character of vanity of vanities has been so strikingly written on all of them. In the loose and heterogeneous manner in which they have descended to us, they seem, indeed, to have followed one another without rational aim or intention of any kind." The whole subject of treatment is difficult and afflictive. We scarcely know how to reply to the important question,—What plan of cure is a practitioner to adopt when he meets with a case of rabies? but it is necessary to attempt an explanation of the mode of treatment which, on the whole, seems to be the most suitable for adoption.

The limits of this article would be extended to a very unnecessary length, were we to do much more than enumerate the various remedies that have been tried in this disease; but a brief notice of them is required, for without a knowledge of what has been attempted, much time must be lost in useless trials and fruitless repetitions.

Amongst the various articles in the *materia medica* which have been employed for the relief or cure of hydrophobia, *opium* is entitled to be first mentioned. This drug, in various forms and in very large quantities, has had the most full and ample trial; but experience has too often proved its inefficacy in

this disease. Dr. Vaughan exhibited fifty-seven grains of opium in the course of fourteen hours with little or no effect upon the symptoms; and in one case Dr. Babington administered one hundred and eighty grains in eleven hours, without any benefit, and without even procuring sleep.* In another instance Dr. Marcet gave opium, iron, and arsenic, to a great extent, but with a like unsuccessful result. Majendie introduced opium in large quantities into the veins of rabid dogs, but without producing its ordinary narcotic effect; and Dupuytren and he afterwards injected eight grains of the extract of opium, in solution, into the crural vein of a young man labouring under hydrophobia in its severest form; but the experiment only afforded temporary relief, for he expired on the fifth day from the attack of the disease. Dr. Richard Pearson strongly recommends the injection of warm water in very small quantities, and impregnated with narcotic substances, into the veins of hydrophobic patients, for the purpose of subduing the spasms which prevent deglutition. This object being attained, he proposes the administration of a strong cathartic, copious dilution with mucilaginous liquids, camphor, and other antispasmodics; and after the operation of these medicines, sponging the body with cold water and vinegar, and giving at the same time internally the nitric or muriatic acids, and lastly some of the vegetable tonics. Dr. Booth considers the acetate of morphia as far preferable to opium for injection into the veins of the hydrophobic sufferer, as its dose and powers are more definite than those of the latter drug. In conducting the injecting process, he suggests that twenty-four minims of the solution of acetate of morphia (equal to four grains of opium) mixed with two drachms of distilled water, be introduced into the cephalic vein; and then, after waiting for about ten minutes to observe the effect, that the operation be repeated at like intervals until a decided sedative impression be produced.† Dr. Brandreth made trial of injection of the acetate of morphia, as recommended by Dr. Booth, in a well-marked instance of hydrophobia, and found that it mitigated the sufferings of the patient in a most decisive manner. In a case of more recent occurrence, we have ourselves witnessed the injection of the acetate of morphia, but we regret to say that it altogether failed in diminishing the violence of the symptoms and retarding the fatal progress of the malady. The operation was skilfully performed by a very respectable surgeon, Mr. Barton, in the presence of Dr. Hull, Mr. Fernely, Mr. Boutflower, jun., and other medical gentlemen. Dr. Ward has strongly advised opiate frictions in hydrophobia; and in more than one instance they have succeeded in calming the irritability of the system, and obtaining a temporary abatement of the distressing spasms of the muscles of respiration and deglutition. Upon the whole, it may be

* Medical Records and Researches.

† Booth on Hydrophobia.

correctly asserted that opium possesses some claims to future confidence as an antilyssic remedy. *Mercury* is another substance which has been highly lauded for its efficacy both in preventing the disease, and removing it after it has actually appeared. It has been very freely employed internally and by friction, on the authority of Dessault, Kaltschmid, James, Du Choisel, Andry, Selig, Königsdörfer, Walther, and other writers; but unfortunately (as an able reviewer justly observes) there are too many cases on record of persons in whom the external wound has been improperly managed, dying of this complaint, notwithstanding the exhibition of large doses of mercury, to warrant much reliance on this remedy alone.* *Belladonna* has also enjoyed the reputation of a valuable remedy in hydrophobia; but the success which seems to have attended the administration of this drug in the practice of Brera and Massalien, has not been present in a number of cases observed by different physicians. *Acids* (particularly the oxymuriatic and acetic) have been freely used and warmly recommended by Aselli, Previtali, and Brugnattelli; but their inefficacy has been proved in several instances. In the case of a young man named Brassendale, which came under the notice of Dr. Bardsley, the aqueous solution of chlorine was fairly tried, but with an unsatisfactory result. *Alkalies, cantharides, antispasmodics*, as camphor, assafetida, musk, and castor; *diuretics, oil*, internally, and by friction; *arsenic, prussic acid, stramonium, white hellebore, acetate of lead*, and the *warm bath*, have also been used, but with no better effect. *Venesection* has long been considered a powerful remedy in hydrophobia, and has been frequently employed to a very great degree. It has been chiefly advised by those authors who believed in the inflammatory nature of the disease. Mead, Nugent, Fothergill, Shadwell, Ferriar, Hartley, Innes, and more recently Tymon and Schoolbred have been the warmest advocates of an early and vigorous use of the lancet; and several cases have been quoted, on the authority of some of these writers, in proof of the efficacy of the practice. Having carefully perused these histories, we feel a difficulty in admitting that the patients were really rabid. Rutherford, Parry, and Troillet have employed profuse and repeated depletions, sometimes even to deliquium, but without any curative result. Indeed, the evidence of Troillet on this point may be deemed conclusive. "Gueyette," he relates, "a été saigné trois fois jusqu'à défaillance, et malgré la perte de sept livres de sang, la rage a continué sa marche funeste. Une terminaison si contraire à celle que nous avons lieu d'attendre nous a fait jeter un regard plus attentif sur l'observation du Docteur Schoolbred; elle n'a pu soutenir l'épreuve de l'analyse; et nous sommes convaincu que son auteur s'est laissé égarer, comme Nugent, par quelques symptômes, qu'une erreur trop com-

mune a fait attribuer exclusivement à la rage. La saignée à défaillance, que des médecins célèbres avoient déjà conseillée, sera abandonnée de nouveau."* It appears also from the experiments of MM. Majendie, Dupuytren, and Breschet on rabid dogs, that profuse venesection was of no avail in arresting the disease. The *cold affusion* has been attended with palliative effects. In the case of Nixon, who was admitted into the Manchester Royal Infirmary, the patient experienced much relief from having cold water dashed upon his body. He not merely stated how grateful the practice was to him in removing the burning heat of skin and other distressing symptoms, but even solicited its occasional repetition. *Electricity and galvanism* have also produced a diminution of suffering in more than one example of hydrophobia. In less than half an hour from the period of the electrical machine being put in motion, Dr. Bardsley's patient, Warren, became more calm and tractable, and expressed a desire to drink some water, which he was able to perform with comparative ease and readiness, and with no small marks of pleasure and even triumph.† *Tobacco* has occasionally been prescribed, and with apparent benefit. The fumes of the plant have been introduced into the rectum; an infusion of the leaves has been employed in the form of enema; and it has been applied externally as a cataplasm to the scrobiculus cordis. Though this drug has failed in preventing the fatal termination of the disease, still it has been shown to have the power of controlling the violence of the spasmodic actions of the muscles of the throat. The *guaco juice* has been highly spoken of by Sir Robert Kerr Porter as a cure for this affection; but it has been freely exhibited in the London hospitals in more than one instance of hydrophobia, and without success. A few months ago, Dr. Elliotson employed this remedy, but it totally failed. That able physician has also prescribed the *carbonate of iron* in large doses. One hydrophobic patient took nine ounces of the carbonate in the course of eighteen hours, but it proved equally inert. In the case of a boy under the care of Mr. Brownbill, to which we have before alluded under the head of pathology, we made trial of the *strychnia*; but it seemed to exert little or no influence upon the symptoms. In this instance the inhalation of the *nitrous oxide gas* was also attempted on the suggestion of Mr. Jordan, and produced for a short time some degree of exhilaration and a propensity to laughter; but owing to the extreme difficulty experienced in continuing the process, the further effects of the gas were not ascertained. Dr. Bright has advised the adoption of *mineral tonic* remedies combined with some of those diffusible stimuli which are useful in calming the irritability in many hysterical attacks. He has proposed the injection of the muriated tincture of iron into the rectum, as being a powerful chalybeate, and in some cases possessing the quality of

* Edinburgh Medical and Surgical Journal, vol. xxi.

* Traité de la Rage, p. 367.

† Medical and Physical Journal, vol. xiii. p. 159.

allaying spasmodic action.* *Violent sweating*, through the influence of highly heated air, has been recommended to the notice of the profession as a remedy in this affection; but we are not aware that it has been sufficiently tried to enable us to determine its real claims to further use. We have seen the hot air bath of great advantage in a very severe instance of traumatic tetanus; and hence it may be deserving of trial in hydrophobia. *Tracheotomy* has been proposed by Mr. Mayo, as an experiment in this malady. Dr. Hunter has alluded to two cases in which the relief obtained by *running* was very remarkable; in one the amendment was so considerable, that the patient did not look like the same person after running about a quarter of a mile. This experiment, however, has not been since adopted.

Having arrived at the conclusion of our inquiry into the history and treatment of rabies, and examined the various means that have at different times been proposed, with the view of arresting the progress and subduing the symptoms of the disease, it is painful to be obliged to confess that no specific or successful mode of cure have up to the present period been discovered. It has been shown that men of the first eminence have directed their utmost attention to the subject, but have unhappily failed in establishing a remedy for this justly reputed opprobrium of medicine. Under these circumstances, humanity seems to dictate the adoption of those measures which best serve to soften the torments of the unhappy patient. As far as we are capable of judging from recorded facts, we should say that the liberal administration of stimulants and cordials, the internal exhibition of opium in very large doses in the interval of the exacerbations, injection of narcotics into the veins, opiate frictions and opiate clysters, abstraction of blood from the upper part of the spine by cupping, electricity, the tobacco injection, and the cold affusion, are the means which have had the most decided power in producing a remission of the more distressing symptoms of hydrophobia, and thus alleviating the agonies of the wretched sufferer.

We think there is reason to hope, from the more correct information we have of late obtained respecting the manner in which the disease affects the animal, and from the frequent and careful performance of experiments with the virus itself, that a more intimate acquaintance with the nature of the poison may yet be obtained, which may at length lead to the establishment of a successful method of treatment. In order to forward so desirable a result, it becomes each member of the profession to make new experiments on the subject; to watch with minute attention every case that occurs in the course of his practice; faithfully to notice every circumstance of importance connected with the malady, and to adopt any untried plan of cure founded on rational principles. "It would, perhaps, at length con-

tribute," the late Dr. Fothergill has justly remarked, "to remove this uncertainty, if those who are applied to on these interesting emergencies would consider themselves as obliged, by the honour of their profession and the ties of humanity, to note with all possible precision and impartiality every incident in the progress of this disease; and whether they pursue the hints here suggested, or take up more rational ones from their own store, would communicate the result to the public. By this method, the field of conjecture would be contracted, and our successors directed to new objects of investigation. The result would be not less honourable to those who engage in the search, than beneficial to mankind in general."

The prescribed limits of this article will not permit the consideration of the several judicious plans which have been proposed by some eminent and enlightened members of the profession for extirpating canine madness from the British isles.

(J. L. Bardsley.)

HYDROTHORAX.—From *ὑδρῶς*, water, and *θώραξ*, the chest. *Water in the chest*. This term is now confined to designate the effusion of serum into the cavities of the pleuræ.

Although so celebrated an author as Laennec has divided hydrothorax into idiopathic and symptomatic, we are by no means inclined to coincide with his views. If idiopathic hydrothorax mean any thing, it means a disease in which effusion of serum is the only affection, and in which there is neither inflammation of the pleuræ nor serious disease in any other organ. Such an affection we have never seen, nor have we found upon record any satisfactory example of it. At the same time Laennec himself has stated that even in the dead body it is not always easy to distinguish between this, which he terms hydrothorax, and chronic pleurisy; the fluid effused exhibiting every variation from a limpid, pellucid serum to concrete albumen in the form of false membranes. Dr. Forbes has observed, in a note to this place in his translation of Laennec, that English authors are better acquainted than the French with the inflammatory origin of many dropsies; and from the hint thrown out, we have little doubt but that with us he is inclined to refer all such cases to different degrees of pleurisy. That effusion of serum is the first symptom in this disease Laennec himself has stated, and that he has found it so marked as to dilate the chest within a few hours from the commencement of inflammation. The cases also which he has given as illustrating idiopathic hydrothorax tend still more to confirm this view of it; for although the first patient recovered once under the use of acetate of potash, she had in a few months afterwards a fatal attack of pleuro-pneumonia on the right side; thus shewing a tendency to inflammation in the pleura; and her recovery on the former occasion might have been owing to the effusion which thus, if we adopt Dr. Parry's views, resolved the inflammation. In the second case, not only had the patient

* Medical Reports, part ii. p. 607.

suffered from organic disease of the heart, but while the lower two-thirds of the right pleura contained a limpid fluid, the upper portions were united by plentiful cellular tissue, which was strong and obviously of long standing, and necessarily the result of previous inflammation. Rayer, in the article *hydrothorax* in the *Dictionnaire de Médecine*, also adopts this view of the affection we are considering, and remarks, that although Lieutaud has noticed four cases out of seventy in which no organic lesion is mentioned, yet they are related with so much brevity as to leave very considerable suspicion of their being incomplete; more especially as Morgagni has not left a single example of hydrothorax in which some such lesion did not exist. For a more complete development of this part of our subject, we refer, therefore, to the article *PLEURISY*, (for the affection in question is really a pleurisy, and must be treated upon the principles applicable to that disease,) only here calling particular attention to what appears to us to be the fact, that there is no such disease as hydrothorax independent of inflammation of the pleuræ or organic disease of some other part.

That affection, however, which Laennec has termed *symptomatic hydrothorax*, is of very frequent occurrence, and, to use the language of this author, there is scarcely any disease, acute or chronic, general or local, in which it may not exist. Affections of the lungs and of the heart, however, are those which it most frequently accompanies, and it is by interfering with their functions that suspicion of the presence of effusion is often first excited.

In this as in most other diseases, no one symptom will suffice to detect its existence: we must have recourse to its past history as well as to its present state; and when the symptoms appear to fail us, the greatest advantage may be derived from percussion and auscultation.

Symptoms and diagnosis.—Were we accurately to speak of the symptoms of hydrothorax, we should be compelled to say with Laennec, Rayer, and other modern authors, that there is really no symptom of the disease excepting oppressive dyspnoea. It would, however, be dismissing the subject too hastily to remain here, for we may certainly trace its history somewhat more satisfactorily.

As we have already stated, that which has been termed *hydropleuritis* is, in fact, an acute pleurisy, and the fluid effused is ill-maturated pus, or serum mixed with the common products of inflammation, pus and coagulable lymph. In all these cases also the pleuræ exhibit more or less alteration, in being more vascular than usual, or in being covered with factitious membranes more or less firm. When, therefore, the fluid poured out in such cases is very considerable, they must be regarded, not as dropsy of the chest, but as cases of empyema, and will require the treatment appropriate to this affection. (See *EMPYEMA*.) Omitting, therefore, any farther mention of these cases, we proceed to the history of symptomatic hydrothorax.

As this is the consequence of a great variety of maladies, so the early symptoms are rather referable to the original disease than to the effusion. Thus, when effusion follows disease of the heart, the early dyspnoea, the starting during sleep, the inability of lying down, the difficulty of mounting an ascent, are dependent upon the original malady, and are frequently observed when little or even no fluid is discovered in the cavities of the pleuræ. These symptoms are, however, unquestionably aggravated by the supervention of dropsy, and when the latter originates from organic disease of the heart, it is itself an additional source of exhaustion to the system, and materially accelerates the fatal termination.

To whatever affection of the thoracic viscera hydrothorax is to be traced, the earliest symptom of effusion is an oedematous state of the eyelids, occurring chiefly in the morning. This is sometimes so little remarkable, that it escapes attention until inquiry be made by the medical attendant; and often it is only remembered when the feet and ankles have been observed to swell in the evening. That there is no exception to this rule we will not venture to assert, but in all the cases which have been presented to our notice, we have never yet met with any. The progress of the disease from this point is exceedingly variable, and this variableness seems to depend much upon the nature of the original affections. In diseases of the heart the early progress is usually slow, the breathing being manifestly more difficult than before the external oedema was perceived, but for some time not aggravated in any remarkable degree. Gradually, however, the external oedema increases, and, *pari passu*, the thoracic oppression, the difficulty of lying down, the dyspnoea, &c. become more distressing. At first, probably, little attention is paid to the difficulty of assuming the recumbent posture, the patient satisfying himself with having his head raised by more pillows. The necessity for having additional pillows continually augments, till at length perfect orthopnoea is established, and he is only able to sleep in a chair. The dyspnoea undergoes also at times very severe exacerbations, the cause of which is not very readily ascertainable. In a tray painter, whom we examined a few years ago, these paroxysms came on every morning between two and three o'clock, and lasted for an hour or more. He was compelled by the sense of suffocation to start out of bed, and while the attack lasted he placed himself against an open window, gasping in the most terrific manner for air. We saw him only three days before his death, which took place suddenly, and on examination the lungs were found to be oedematous; upwards of two quarts of serum were contained in the cavities of the pleuræ, and a few ounces of coffee-coloured fluid in the pericardium. The only other morbid appearance in the whole body was hypertrophy of the left ventricle. While the symptoms now referred to continue to increase, the face likewise becomes more and more oedematous; the cheeks assume a purple hue,

and the lips become livid and at times almost black. The duration of this state varies considerably in different individuals, sometimes lasting for weeks without any alleviation of symptoms, sometimes admitting of great relief by medicine, and intervals of almost perfect ease; at other times its progress is extremely rapid, a few days only intervening between the first symptoms of effusion and dissolution. The termination is in many cases very sudden, and in fat individuals sometimes a very slight effort is sufficient to break the thread of life. It is no unusual circumstance for such persons to die while in a privy, apparently in the act of evacuating the bowels, the slight straining which they are then compelled to make being more than the system is able to bear.

In the symptoms which we have now enumerated, we have endeavoured as much as possible to confine ourselves to those which may fairly be regarded as the consequence of effusion. They are, however, in general so much complicated with the symptoms of the original disease, that probably, notwithstanding these precautions, we may have been led into error. It must, however, be remembered that the original disease during this time is not stationary. Valvular concretions may continue to increase; aneurisms become more and more dilated; or whatever other organic change the heart may be the subject of, be proceeding, independently of effusion, to a state inconsistent with health and life. Accordingly, the symptoms of these changes are aggravated at the same time: the palpitations become more frequent and more severe; frightful dreams, sudden starting from sleep, &c. &c. more and more marked; and the vital powers are manifestly daily yielding. It ought not to be forgotten that these two diseases thus acting upon each other, may give rise to such a congestion in the lungs as will be best relieved by bleeding. Much caution and attention, however, ought to be paid to the state of the patient before we conclude that this is the case, since if bleeding be unnecessarily resorted to, it will unquestionably debilitate the patient and hasten his dissolution.

What we have now said refers to hydrothorax as dependent upon disease of the heart; it sometimes, however, succeeds to bronchitis and pneumonia; and in this case the progress is somewhat different. The palpitations and other cardiac symptoms are usually wanting, and there is nothing more manifested than increased dyspnoea. Previously to this becoming very marked, however, the face and feet swell as in the former instance; the patient then requires the head and shoulders to be raised, and at length, as in the former case, he is unable to lie down at all, but remains constantly in a sitting posture. In these cases the termination is seldom so sudden as when the heart is diseased, neither does the countenance exhibit in the same degree the purple and livid appearance. This, however, may be owing to the fact, that the effusion is seldom so great when the consequence of disease of the lungs, as when attended by cardiac disease;

and it seldom occurs till the original disease has so far weakened the system as of itself to threaten a speedy termination.

In addition to the symptoms and history now given, we have yet farther means of diagnosis in succussion, percussion, stethoscopic auscultation, and admeasurement.

Succussion, as has been already explained under the article AUSCULTATION, consists in forcibly shaking the patient's body and observing the sound thereby produced; and, at the same time, to produce any appreciable sound, it requires the presence of both a gaseous and a liquid fluid in the chest. In hydrothorax it can only be serviceable when the cavity of the pleura communicates with the external air through an aperture of the lungs, or when gas is evolved within the same cavity without any such aperture. We are not, however, aware that either of these circumstances has been ever noticed in the real hydrothorax, although the former is common enough in empyema arising from the bursting of a pulmonary abscess into the cavity of the pleura.

Percussion returns a dull and flat sound over every part of the chest where there is effusion, and the extent of the effusion may be partly judged of by the extent of surface which affords the dull sound. There are, however, many other diseases of the chest besides hydrothorax which prevent percussion from affording the healthy degree of resonance, and to distinguish hydrothorax from these we must be indebted to other means, and among these the stethoscope is one of the most valuable.

The stethoscope, if employed very early, and while yet the effused fluid is in very small quantity, affords that peculiar sound of the voice which Laennec has termed *egophony*. This, however, will very rarely happen, for usually the effusion is considerable before application is made for assistance. The only information which the stethoscope affords under these circumstances, is a want of respiration every where excepting at the root of the lungs.

When, however, we have thus learned from percussion and stethoscopic auscultation that the lungs are impeded in their functions, we have yet to learn what the change is which thus prevents the ingress of air, whether the impediment arises from condensation of their substance, whether from empyema or real hydrothorax, or from any other cause, such as aneurisms, tumours, &c., compressing their substance. In order to arrive at this information, we must estimate the general symptoms and those afforded by percussion and stethoscopic auscultation together.

In the article EMPYEMA, the principal affections have been enumerated which might be confounded with that disease, as tubercular consumption, hepatization of the lungs, tumours in the cavities of the pleura, &c.; and for the most part the same means of distinction exist between these affections and hydrothorax. It still remains to be shewn what means are afforded us of distinguishing empyema from hydrothorax, and this can only be done by an

accurate investigation of the preceding symptoms.

In hydrothorax the serous diathesis always prevails, and there is, at the same time with effusion into the cavities, effusion in the cellular tissue either of the face and ancles only, or of the extremities, sometimes of the whole surface of the body. Now, even in empyema we may also have anasarca partial or general, but upon inquiry we shall in this case find that the symptoms of the chest have long preceded the appearance of dropsy, and the latter, instead of appearing the direct consequence of the thoracic disease, would rather appear to be the mere result of debility;—the cough, the dyspnoea, the emaciation especially, having usually proceeded to an extreme before there was the slightest appearance of effusion. In hydrothorax, on the contrary, the appearance of œdema of the face and ancles long precedes the more severe affection of the chest: sometimes even the ancles attract attention for a little while by swelling, and then subside for a considerable interval, or they swell so slightly as to be forgotten. In empyema, again, the stethoscope will usually prove that respiration is well carried on in one lung at least, although the other may be perfectly useless. This, however, can seldom happen in hydrothorax; and were we to judge from our own observation, we should even be inclined to say that it never happens. Whenever hydrothorax exists to any extent, that is, whenever there is any considerable quantity of serum in the cavities of the pleuræ, the lungs participate in the dropsical disposition, and fluid is effused into their cellular texture. This must, therefore, materially impede respiration, and as it must exist nearly equally in both lungs, there can never be the decided difference between the two sides that is observable in empyema.

Perhaps we ought not to omit all mention of *admeasurement*, more especially as effusion, real dropsical effusion, may exist to a much greater degree in one side than in the other. That side in which the effusion is greatest will certainly be more dilated than the other, as is the case in empyema; but if with this difference of measure we unite the indications of the stethoscope, we cannot be in much danger of confounding the two affections.

Bichat has recommended an experiment in doubtful cases of hydrothorax which deserves some notice, especially in distinguishing it from empyema. This consists in placing the patient in an horizontal position, and pressing upon the abdomen from below upwards, thus limiting the descent of the diaphragm. The fluid effused into the pleuræ is thus forced to compress the lungs, the sense of suffocation becomes most painful, and the countenance assumes a livid hue. Now as distinguishing hydrothorax from any diseases occupying both sides of the chest, this appears scarcely available; but in distinguishing it from empyema, which occupies only one side, it may be a most valuable resource. Dr. Townsend, in the admirable paper upon empyema, to which we have before

referred, remarks that if the pressure be made on that side in which effusion is present, no result follows, because this side being already useless, no additional pressure can add to the inconvenience; but if it be made on the sound side, this being the only side which is useful for respiration, the expansion of the lung is prevented, and the utmost distress induced. In distinguishing hydrothorax, then, from empyema, much use may be made of this experiment, although it by no means answers in the manner which its celebrated author proposed.

Prognosis.—The prognosis of hydrothorax is always unfavourable, because it is never a simple disease, but always the consequence of some other malady, which would, even without effusion, eventually terminate in death. This opinion, however, is only applicable to a complete restoration to health, for to a comfortable state it is frequently in the power of medicine to restore the patient. So far as the mere effusion is concerned, it may in many cases be removed again and again; and as this is often the most threatening source of danger, the prognosis may for a time be reversed. Still every fresh occurrence of dropsy of the chest makes even a temporary recovery less probable, and in giving any opinion of the disease we must take into our consideration both the stage of the original disease and the frequency with which effusion may have occurred. Under all circumstances our opinion ought to be most guarded, and it is at least wise never to omit the announcement that death may be sudden.

Appearances on dissection.—If we were to enumerate all of those which are at different times found in hydrothorax, we could scarcely omit any long exhausting disease of the human body, certainly none of the thoracic viscera. This would, however, be proceeding much farther than would be useful. Some diseases, however, are much more liable to terminate in hydrothorax than others, and such are those in particular of which the heart, the great bloodvessels, and the lungs, are the subjects. Accordingly, valvular disease of the heart, active and passive aneurisms of the same organ, aneurisms of the aorta and arteria innominata, chronic bronchitis, and tubercular consumption, are more frequently met with than any other organic changes in hydrothorax. Some changes are also observable in the state of the pleura, but this is only very manifest when actual inflammation has been present. We have seen a vascular state of this membrane, and various degrees of factitious membrane deposited upon it.

The quantity of fluid varies very considerably, and in our experience it has always been greater when dependent upon disease of the heart and great bloodvessels than on any other cause. M. Itard places the largest quantity at twelve or fourteen pints, and Portal quotes a case from Wolfius in which sixteen pints were found. Morgagni seldom mentions the precise quantity, but usually states it at some pounds. With one exception, the largest quantity we have met with did not exceed nine pints. In the excepted case, which was an

aneurism of the arteria innominata, the quantity effused must have been at least fourteen or fifteen pints.

The colour of the effused fluid is usually amber, sometimes, however, mixed with coagulable lymph, but this only happens when there has been inflammation of the pleura. Laennec has indeed very justly observed that from the appearance of the effused fluid alone it is not always easy to decide whether the affection has been hydrothorax or empyema, the serum assuming many grades between a limpid fluid and coagulable lymph. This fact is of great importance in practice, as Dr. Forbes has remarked: it is essential that the physician remember that the inflammatory and serous diathesis may exist together, or supervene one to the other. The plan of treatment must therefore be varied accordingly.

Like the effusion into the other cavities of the trunk, the fluid is sometimes of a dark coffee colour, sometimes bloody, and assumes every variety of hue between the pellucid serum and blood itself.

Treatment.—The same general principles apply to the treatment of hydrothorax which have been mentioned under the article *Dropsy*. Although the original cause of effusion is an affection of some organ of the chest, or some disorder of the general system, yet the immediate source is the serous membrane, and regard must be had to its condition. Even in a very weakened state of the body the pleura may become inflamed and demand an antiphlogistic treatment. When this is the case, it is an important object of inquiry how far antiphlogistic remedies may be carried with advantage or even with impunity; and upon this point some few considerations present themselves to our notice.

When towards the termination of chronic diseases local inflammation occurs, we have a very different physiological state of the system to contend with from that which would be present should such inflammations take place from an immediately previous good state of health: not only under these circumstances have we no general plethora to overcome, which indeed might happen when the system had not been weakened by disease, but there is a positive wasting and probably actual inanition. Now even in common circumstances it is never advisable to carry bloodletting farther than is sufficient to overcome the immediate inflammation, for although no evil result may be at once apparent, no one can have followed the footsteps of some modern bleeders without seeing the most deplorable consequences of over-depletion. Months and even years are often necessary to restore the system to that equilibrium in which the *mens sana in corpore sano* can again be enjoyed. We have no hesitation in asserting that many of the most lamentable cases of hysteria and habitual nervousness owe their origin to this mis-called heroic practice, and in females particularly that helpless capriciousness, which is so often burthensome to themselves and tormenting to their friends, has been derived from repeated bleedings for pains

in the side, which have upon very slight investigation been referred to the presence of acute pleurisy. If then this happen with persons in health when bled improperly, the consequences of unnecessarily large bleedings in chronic diseases are still more disastrous. In the latter stages of tubercular consumption we have seen patients hurried to their graves by wild attempts to cure a pleurisy, without any consideration of their previous state, and even in pneumonia fatal effusion has instantly followed a large bleeding, when perhaps a moderate one would have restored the individual to health. In the treatment of hydrothorax dependent upon an exhausting organic disease, an error in this respect would be almost certainly fatal, for we well know that hemorrhage, even without previous debility, is one cause at least of dropsical effusions.

By what we have now said, however, we by no means intend to proscribe bleeding in water in the chest, but merely to urge that due caution be practised in employing it. Two circumstances may occur in hydrothorax which may render bloodletting necessary, the occurrence of pleurisy acute or sub-acute, and congestion in the lungs: the latter is peculiarly liable to happen when hydrothorax is connected with valvular disease of the heart. In the former case local bleeding is always preferable, both because it may be taken much more immediately from the seat of disease, and also because it has less effect upon the general strength of the system. Another advantage is derivable also from cupping, which neither general bleeding nor leeches are calculated to afford, and this is a more permanent determination of blood to the external surface from the action of the cupping glasses. That cupping has a decided advantage over leeches need hardly be mentioned. In our opinion the latter never ought to be used when the former can be employed. Both the quantity of blood taken is more satisfactorily ascertained, and the patient is not fatigued or inconvenienced in any degree equal to what is the consequence of employing leeches.

When it is necessary to draw blood on account of congestion in the lungs, recourse must be had to general bloodletting, and the quantity must be guided by the effect upon the disease. We know of no very certain sign that this congestion has place when hydrothorax is present, excepting the occurrence of hemoptysis; and wherever this happens with valvular disease of the heart, we should not hesitate to bleed, and it will usually be found advisable to repeat the bleeding at longer or shorter intervals. In general it will be necessary to take only a small quantity of blood at a time, sometimes not exceeding six or eight ounces; but the benefit afforded by this is very decided, and the debility induced is not enough to prevent recourse being again and again had to venesection for relief.

Purgatives and diuretics naturally suggest themselves as the medicines most likely to afford relief in hydrothorax, and to each belong advantages which are not possessed by the other.

The relief afforded by elaterium and croton oil is unquestionably much more speedy than that which can be obtained by the employment of diuretics. Unfortunately, however, they exhaust the patient in a much greater degree, and cannot be safely employed in a very debilitated condition of the system. The mode of giving elaterium has been mentioned under the articles anasarca and dropsy, and we have nothing to add to the observations there made. We may make a similar remark regarding digitalis and other diuretics. Here we will do no more than repeat what we have frequently said already, that the dropsy is only symptomatic, and that it is to the cure of the original affection that we must look for the perfect restoration of the patient; and our success in practice will mainly depend upon the accuracy of our diagnosis as to the original cause of the effusion.

The last point to which we shall allude in the treatment of hydrothorax is the propriety of tapping, an operation which we can scarcely conceive applicable to genuine hydrothorax. Most of the cases in which paracentesis thoracis has been employed, were in fact cases of empyema; and unquestionably there are many instances on record in which complete success was obtained by its performance. In the article hydrothorax, in Good's Study of Medicine, we have but another instance in addition to those referred to by Dr. Forbes, of practitioners confounding empyema and hydrothorax together. He has mentioned a successful case by Dr. Arthur of Dublin, which, without doubt, was an instance of empyema, as it had been the result of a preceding pleurisy. But empyema is usually confined to one side of the chest, the opposite lung being comparatively healthy; and hence, by drawing off the fluid, we have some chance of the compressed lung recovering itself, and we at least take off any inconvenience which may arise from the quantity of fluid narrowing the cavity of the sound pleura. In hydrothorax, on the other hand, both sides are affected, though perhaps not in an equal degree; and whenever the effusion is sufficiently great to suggest such an operation, there is the greatest probability that the cellular texture of the lungs themselves is likewise the seat of effusion. Hence it must be always doubtful to which the dyspnoea ought to be referred, effusion within the cavities of the pleura, or effusion within the cellular tissue of the lungs; and at the best, the usefulness of the operation must be very problematical. It is not, however, very likely that in real hydrothorax it will ever be proposed.

(John Darwall.)

HYPERTROPHY, (from *ὕψις* and *τροφή*, signifying an excess of nutrition,) is a term applied by pathologists to that condition of a tissue or organ which presents an increase of substance, not arising from any transformation of tissue, or from the development of any morbid product, but simply from a preternatural growth of its proper organic textures. For example, a muscle is said to be in a state of

hypertrophy when its size exceeds the ordinary standard, provided it still retains its muscular structure; but the term hypertrophy could not with propriety be applied if the increased size of the muscle were produced by the transformation of its fibres into fat, or by the development of a tumour in its interior.

As hypertrophy is only an increased development of the natural structure, it cannot strictly be considered as constituting a disease, unless when it deranges the functions of the hypertrophied organ, or exercises an injurious degree of pressure on the neighbouring parts. The muscles on the fore-arm of a pugilist or of a blacksmith, though hypertrophied to double their natural dimensions, are so far from constituting a disease, that they afford a good criterion of the health and strength of the individual; whereas there are few diseases more formidable than a similar condition of the muscular walls of the heart. Indeed it is only of late years that hypertrophy has attracted the attention of anatomists as occurring in any other organ than the heart. The accurate researches of modern pathologists have, however, clearly demonstrated that several tissues, especially the muscular, the adipose, the cellular, the mucous, the cutaneous, the nervous, the vascular, the fibrous, and the osseous, are liable to this affection; and that any organ into whose composition these tissues enter, may be generally hypertrophied throughout its entire structure, or may have the hypertrophy confined to one or more of its component parts. Sometimes, indeed not unfrequently, it happens that by virtue of a sort of balance in the nutritive powers of the part, in proportion as one tissue is hypertrophied another becomes atrophied, in which case the original structure of the organ is so completely changed, that it becomes exceedingly difficult to recognise it. In hypertrophy of the white acini of the liver, accompanied with atrophy of the red acini of the same part, the natural appearance of the organ is materially changed; and in those cases where its cellular tissue is so hypertrophied as to form large masses of a pearly white colour, intersected by opaque membranous septa or partitions, producing an appearance not unaptly compared to the section of a turnip, the natural structure of the viscus is so completely altered that pathologists have not hesitated to refer the alteration to the development of the non-analogous accidental production named scirrhus.

As the effect of excessive nutrition is to increase the number of molecular atoms which enter into the composition of the part, it generally follows that a tissue or organ in a state of hypertrophy becomes thicker and larger than in its natural state. Sometimes, however, the effect of hypertrophy is to increase the density rather than the bulk of the part, as is exemplified in hypertrophied bones, which occasionally become as dense and as compact as ivory, without undergoing any change in their external form or dimensions. Indeed the size of an organ would in many instances afford a very erroneous index of the state of its nutrition, for we know from observation that the hollow organs may be

in an extreme state of hypertrophy without having their size apparently increased, in consequence of the supernumerary particles being deposited on their internal surface, and at the expense of their cavities, as in concentric hypertrophy of the heart: and that, on the other hand, these organs may be greatly increased in size without being in the slightest degree hypertrophied, as is exemplified in the skulls of hydrocephalic persons, and in passive dilatations of the heart, bladder, stomach, &c.; in all of which cases the parietes of these organs are in fact thinner than natural, and their increased size is produced by mechanical distention independently of any increase in the number of their integrant particles. Thus it appears that the natural cavity in a hollow organ may remain unaltered in its dimensions, or may have its capacity either increased or diminished, at the same time that its parietes are hypertrophied. When the dimensions of the cavity remain unaltered, the thickness of the walls, as compared with their ordinary standard, will afford a correct index of the state of their nutrition; when the capacity of the cavity is diminished, the walls may appear considerably thicker than usual, in consequence of the contracted state of their muscular fibres, independently of any increase of substance; and on the contrary, when the cavities are much enlarged, their walls may appear thinner than usual, when in reality their substance is increased, though from its excessive distention it is apparently diminished.

But it is not in the hollow organs alone that an alteration of size may take place independently of any increase of the nutritive function, for considerable enlargement is often produced in various organs by an accumulation of blood in their capillary vessels. There is perhaps no viscus that exhibits this enlargement from congestion in a more marked degree than the liver, especially in those cases where any obstruction exists to the free exit of its blood. We recollect one case, particularly, of aneurism of the aorta compressing the inferior vena cava so as to obstruct considerably the flow of blood from the liver, in consequence of which that organ was enlarged to such a degree as to descend almost to the crest of the ilium. Suddenly, however, the aneurism gave way, and the pressure being thereby removed from off the cava, the hepatic veins were allowed to unload themselves, and the liver had nearly resumed its natural situation and dimensions when the post-mortem examination was made. The spleen is likewise often greatly increased in size by the accumulation of blood in its interior. We have repeatedly observed this effect produced in those cases where the liver was small, indurated, and knobbed on its surface. Another reason why the size of an organ does not always afford a correct criterion of the state of its nutrition is, that the hypertrophy is often confined to one elementary tissue of the part, while one or more of the other tissues which enter into its composition waste away and fall into a state of atrophy, which more than compensates for the increased size of the hypertrophied tissue.

Instead of increasing either the size or den-

sity of the hypertrophied tissue, it sometimes happens that the exuberance of nutrition is manifested by the formation of vegetations or projections from its surface, as in fungoid excrescences of the mucous membrane, exostosis, &c.

Hypertrophy may exist simple and uncombined, or may co-exist with other alterations of the tissue or organ affected; thus it may be combined with hyperæmia, or on the contrary with anæmia; hence it is that we sometimes find the parts affected of their natural colour, sometimes presenting different shades of red or brown, and sometimes, also, colourless and exanguinous. In like manner their consistence is in some cases unaltered, in others, (and they are the most numerous,) increased, and in others again diminished, the tissue hypertrophied being at the same time in a state of softening.*

We shall now proceed to consider briefly the principal alterations produced by hypertrophy in the different tissues and organs, the causes which seem to favour its production, and the effects to which it commonly gives rise.

Hypertrophy of the muscles.—The effect of hypertrophy on a muscle is in general to increase its size and render it firmer than ordinary; its fibres become more condensed, contain a larger proportion of colouring matter, and a less quantity of serous fluid; the fat deposited in the interstices of the muscles usually diminishes, while the bloodvessels undergo an increase of size proportioned to the extent of the hypertrophy. Such are the alterations which the muscles of the pugilist undergo during the process of *training*, as it is termed, and such is also, to a certain extent, the condition of any muscle or set of muscles kept in constant and active exercise. On this principle is founded the system of gymnastic exercises, which, when judiciously conducted, have been found so efficacious in improving the strength and correcting the tendency to deformity so often arising from irregular or defective muscular development. Unfortunately, however, it is not the voluntary muscles alone that are liable to hypertrophy; the muscular structure of the heart and of the air-tubes, of the intestinal canal, and of the bladder, are likewise subject to this affection, and in them it is often productive of the most distressing and dangerous consequences. In these musculo-membraneous organs we constantly find hypertrophy of the muscular fibres produced by any cause, whether organic or functional, which increases the frequency and energy of their contractions, provided it continues to act for a sufficient length of time. Thus, diseases of the valves of the heart or of its great vessels, by opposing an obstacle to the exit of the blood, stimulate its muscular parietes to increased action, in order to overcome these obstacles, and this increased action eventually leads to their hypertrophy; but the same effect may likewise be produced by long-continued palpitations arising from mental emotion, or from any other cause whatever. (See HYPERTROPHY OF THE HEART.)

* *Andral, Pathol. Anat.*

In the same way hypertrophy of the muscular fibres of the bladder is produced by any obstacle to the evacuation of its contents, such as enlarged prostate, fungous tumours, or strictures of the urethra, which obstruct the passage of the urine, and so stimulate the bladder to increase its efforts in order to propel its contents; the same effect is also produced by the presence of calculi or gravel, or by any other cause which irritates the bladder directly or sympathetically, and causes it to contract with greater force and frequency than natural. When the bladder is thus affected, its muscular coat may be uniformly thickened, or the hypertrophy may be confined to certain fasciculi which project from its surface like the muscoli pectinati of the auricles, and give the interior of the organ a remarkable sacculated appearance. These fibres never acquire the red colour which muscles of the same size have in other parts of the body when hypertrophied by exercise; but like the muscular fibres of the intestinal tube, they remain pale, even when hypertrophied to an extreme degree. The muscular fibres of the bronchi likewise acquire an excessive development from the increased exertions which they are called on to make during protracted attacks of dyspnoea or of violent coughing. In old asthmatic persons, and in the still more numerous class of patients who suffer repeated attacks of dyspnoea from organic disease of the heart and congestion of the bronchial membrane, we have constantly found the transverse muscular fibres of the bronchi, which in the natural state are scarcely perceptible, so increased in size as to form distinct fasciculi.

Another frequent cause of hypertrophy of the muscular parietes of these organs is *inflammation*, especially when of a chronic character, and affecting their lining or investing membranes. Thus pericarditis, terminating by the formation of adhesions, is often followed by hypertrophy of the heart; and though it is difficult to adduce positive evidence that inflammation of the internal membrane of the heart is capable of producing hypertrophy of its walls, yet the conclusion is almost justified by analogy. The effect of chronic inflammation of the mucous membrane of the bronchi in producing hypertrophy of the subjacent muscular fibres has already been noticed. A similar effect is frequently produced by irritation or chronic inflammation of the mucous membrane of the bladder, arising from the presence of calculi, &c. In chronic dysentery the muscular fibres of the colon are in general greatly hypertrophied. Hypertrophy of the muscular coat of the stomach is also frequently produced by chronic irritation of the mucous membrane of that viscus.* The hypertrophy of this tunic is usually accompanied with a similar condition of the other submucous tissues, and this state of the viscus is commonly described as the effect of scirrhus degeneration. In such cases, on making an incision through the thickened parietes of the stomach, we find—1. the

times altered in various ways; 2. immediately beneath this, a layer of a milk-white colour, varying in thickness from less than a line to several inches: this is the sub-mucous cellular tissue. 3. Beneath this layer appears another, distinguished by its bluish colour, semi-transparent, and with a peculiar kind of lustre, traversed by an infinite number of opaque lines: this is evidently the muscular coat in a state of hypertrophy. 4. Still more externally there may appear a second layer of a dead white colour and homogeneous texture: this is in fact the sub-peritoneal cellular tissue, which has become thickened and indurated like the submucous. In some cases the cellular tissue remains unaltered, and the muscular coat alone is hypertrophied so as to produce considerable thickening of the stomach or intestines. It is in the pyloric portion of the stomach especially that this form of hypertrophy has been observed; and this is also one of the parts where in the natural condition the muscular coat of the alimentary canal is of the greatest thickness, and its action most remarkable. On opening the abdomen of a living animal we find that the right end of the stomach, the pylorus, and the commencement of the duodenum, are continually animated with a contractile motion. This motion is most distinct during the process of chymification, whence it follows that whatever tends to excite the mucous membrane of the stomach must tend to increase the action of the muscular fibres of the pylorus, and eventually to produce in them a state of hypertrophy.* We have seen these fibres hypertrophied to such a degree as to measure nearly two inches in thickness, and to present a striking resemblance to the gizzard of birds. Dr. René Prus observes that the frequent vomitings which occur in persons labouring under chronic gastritis may contribute very much to produce the hypertrophy of the muscular fibres that so often succeeds to protracted attacks of this disease.†

From whatever cause the hypertrophy of the hollow muscular organs arises, the effect of the excessive development of their fibres is to increase their force and irritability, and consequently the frequency and energy of their contractions. The bladder, when hypertrophied, says Dr. Baillie, becomes extremely irritable, the inclination to make water is frequent, and repeated efforts of the muscular coat are required, which increase its thickness more and more. In like manner the irritability of the transverse fibres of the bronchi is increased in proportion to their increase of development, until the slightest irritation becomes sufficient to excite them to violent contractions. In such cases, any irritation of the mucous membrane produces violent paroxysms of dyspnoea and coughing, which in their turn increase the hypertrophy of the muscular fibres, and so the disease becomes progressively aggravated. Similar effects are likewise produced in chronic

* Andral's Path. Anat.

† Recherches sur la Nature et le Traitement de Cancer de l'Estomac.

* Broussais, Phlegmasies Chroniques.

dysentery by hypertrophy of the muscular fibres of the rectum and colon, until eventually the presence of the least quantity of feculent matter is sufficient to induce the most violent spasmodic efforts for its expulsion.

The symptoms produced by hypertrophy of the heart are of such importance as to merit a special article to be devoted to their consideration; to which, therefore, the reader is referred.—See HYPERTROPHY OF THE HEART.

Hypertrophy of the adipose tissue.—The adipose or fatty tissue is of all others the most subject to hypertrophy: it is in general largely developed in infants immediately under the integuments, but seldom accumulates at that age on the internal organs. After the second or third year the tendency to obesity usually disappears until the period of puberty, at which time, especially in females, it again makes its appearance, though it very seldom becomes excessive before the age of five-and-twenty. It has been calculated* that the average weight of an adult of ordinary robustness is about eleven or twelve stone, of which fat constitutes about one-twentieth part; in some cases, however, it is developed in such enormous quantities as to constitute from one-half to four-fifths of the entire weight: and there are cases on record of persons becoming so prodigiously laden with fat as to weigh from thirty-five to forty stone. M. Dupuytren has published an account of the dissection of a remarkable case of this kind. The individual (who was a poor beggar-woman, totally dependent for her daily sustenance on the precarious contributions of charity,) measured five feet one inch in height and five feet two in circumference. The subcutaneous layer of fat was three inches deep on the thighs, four inches on the glutei, and seven inches on the mammæ. In the interior of the body the only parts which were completely exempt from fat were the skull and the spinal canal. In the thorax there was no fat developed between the fibrous and serous layers of the pericardium; but it was accumulated in enormous quantities at the base and on the surface of the heart, and in the mediastinum, and was also deposited in large masses between the costal pleura and the ribs. The pulmonary pleura contained no fat. In the abdomen, the peritoneum was every where coated with a thick layer of fat, except where it was reflected over the liver, the spleen, and the small intestines: between the peritoneum and the diaphragm it was developed in large quantities, as also between the peritoneum and the muscular coat of the stomach and colon, from the latter of which it hung in fringes two inches long and three quarters of an inch in diameter. In the mesentery it measured two inches, and in the greater and less omentum one inch in thickness. No organ appeared to have undergone the fatty degeneration except the mammary glands. The muscles retained their red colour, and even seemed to have acquired an increased development, as if for the purpose

of increasing their force in proportion to the increased mass which they had to move.* This case exhibits a striking instance of the influence of idiosyncrasy in producing general hypertrophy of the adipose tissue; for the individual in question was scantily supplied with the most meagre diet, and took a great deal of exercise every day; in short led precisely that kind of life which is supposed to be least favourable to the accumulation of fat. Hypertrophy of the adipose tissue may likewise occur as a local affection. We not unfrequently find (more especially in persons advanced in life who have indulged freely in the pleasures of the table) fat accumulated in such quantities in the abdomen, as to give the belly a size altogether disproportioned to the rest of the body. The mammæ in some females are enormously laden with fat; and the quantity of this substance deposited on the glutei muscles is so great in some cases as to constitute an absolute deformity, as in the African woman, named the *Hottentot Venus*, who was exhibited in this country some years ago. Lobstein relates the case of a child, one of whose thighs was so laden with fat as to measure twice as much in circumference as its fellow of the opposite side.†

It seldom happens that fat is developed in such quantities on any of the internal organs as to impede their functions, unless in cases of general obesity; the heart, however, is sometimes greatly overloaded with fat, particularly at its basis, along the septum, and at the apex of the right ventricle. Indeed, this condition of the viscus is by no means uncommon in advanced life even in persons of moderate embonpoint. We have generally found it coinciding with a pale flabby condition of the muscular fibres, and not unfrequently combined with a general dropsical diathesis. It does not appear that this condition of the organ produces any material or permanent derangement of its functions, or that it is characterised by any peculiar symptoms by which its existence may be recognised during life. Fatty tumours are occasionally formed in different parts of the body, and constitute another variety of local hypertrophy of the adipose tissue.

Respecting the immediate or proximate cause of hypertrophy of the adipose tissue, little is known beyond conjecture. Some individuals accumulate fat under circumstances in which others would almost die of inanition. Certain circumstances, however, have been ascertained by experience to be peculiarly favourable to obesity, among which may be enumerated, full living, sedentary habits, and the want of mental excitement. Castration has likewise been observed to promote the accumulation of fat, and the same effect is produced by the removal of the ovaries from the female.

Hypertrophy of the cellular tissue.—The following description of the anatomical cha-

* Dictionnaire de Médecine. Art. *Polysarcie*.

* Journal de Corvisart, tom. xii. p. 262.

† Traité d'Anatomie Pathologique.

racters of this lesion has been borrowed from M. Andral, to whom we are indebted for the first and most accurate account of this morbid alteration of structure.

"The cellular tissue is very frequently affected with hypertrophy: in those parts where it naturally possesses but little consistence, and resembles a sort of organized mucus, it acquires, when hypertrophied, a greater degree of firmness and density; and in the parts where its density is naturally considerable, its laminae and filaments acquire an unusual thickness, become blended together, assume a dull white colour, or a peculiar grey semi-transparent appearance, and offer considerable resistance to the scalpel. When the hypertrophy has arrived thus far, we observe between the organs, or the different parts of the same organ (according to the seat of the disease), a whitish substance in the form of laminae, or of irregular masses, intersected by numerous lines and striæ; and if we examine the structure of these masses, and trace their formation, we find that they are evidently composed of portions of cellular tissue, which become progressively more and more condensed, and finally present the appearance of a homogeneous mass, which, according to its colour and degree of condensation, resembles either the interior of a turnip, with its dull white striæ, the fat of bacon, or imperfect cartilage, such as is found in the fœtus.

"These different alterations of structure have hitherto been confounded under the generic denomination of scirrhus, whereas they are all produced by hypertrophy of the cellular tissue, in some cases simple and uncombined, in others conjoined with some product of a morbid secretion into the areolæ of the cellular texture.*"

Hypertrophy of the submucous cellular tissue of the alimentary canal is very frequently produced by chronic irritation of the mucous membrane, more especially in cases of chronic gastritis and of dysentery. In the urinary apparatus it is also often caused by irritation or chronic inflammation of the membrane to which it is subjacent. Hypertrophy of the submucous cellular tissue of the urethra is one of the most frequent causes of stricture. We have never observed the submucous cellular tissue hypertrophied to any great degree in the air-passages of the respiratory apparatus. The subcutaneous cellular tissue is often very much thickened in the neighbourhood of old ulcers, and of eruptive diseases of long standing. Hypertrophy of the cellular tissue is likewise observed in the parenchymatous structure of several organs: sometimes the proper texture of the part remains unaltered in other respects, and the only change observable is, that the cellular tissue which intersects and supports its structure is rendered thicker, harder, and more opaque than natural. This appearance is often observed in the pancreas, thyroid, and mammary

glands. More frequently, however, the proper tissue of the part falls into a state of atrophy, or even disappears altogether, and the cellular tissue which formed its original frame-work acquires a preternatural development, so as to form considerable masses of a white colour and striated appearance, not unlike the section of a turnip. This alteration of structure we have observed most frequently in the liver and spleen. Another form of hypertrophy of the cellular tissue is that in which one or more of its cells are dilated and their walls thickened, as in the serous cysts which are found in the kidneys and ovaries, and attached to the cho-roid plexus.

Hypertrophy of the mucous tissue.—This is a frequent result of long-continued or often repeated attacks of inflammation. When the mucous membrane of the stomach or intestines is affected with hypertrophy, it generally becomes harder and denser than ordinary, so that it may be torn off in large shreds. This affection is more common in the stomach and colon than in the small intestines: the membrane, while becoming thicker, sometimes preserves a smooth and uniform appearance; sometimes, being thickened unequally, it presents a number of elevations separated by sinuous depressions. In the large intestine the hypertrophy of the mucous membrane is sometimes so excessive that it exceeds in thickness all the other coats taken together. In the small intestines we have seen the valvulae conniventes longer, thicker, and at least twice as numerous as they usually are. When the hypertrophy only affects isolated points of the mucous membrane, it produces elevated patches and tumours of various forms, sizes, and textures, which have been designated by the names of vegetations, fungous excrescences, polypi, &c. according to the forms they assumed, and the varieties of consistence and colour which their texture exhibited.* Sometimes the hypertrophy, instead of involving the entire texture of the membrane, affects only the villi which cover its surface, and in some cases the hypertrophy is confined to the mucous follicles, and the membrane appears studded over with small conical whitish bodies, having each a central pore or orifice in those parts of the intestines where the follicles are isolated; these conical bodies are separate and distinct, but where the follicles are aggregated, they become confluent, and by their assemblage form large clustered patches. Hypertrophy of the follicles occurs most frequently at the lower portion of the small intestines. Like the other varieties of hypertrophy of the intestinal tube, it is usually found in those who have laboured under diarrhœa and other symptoms of local irritation for some period before death.

That portion of the mucous membrane which lines the larynx and bronchi frequently becomes hypertrophied in persons affected with chronic irritation of those parts. The anatomo-

* Op. cit.

* Andral.

mical characters of hypertrophy of this portion of the membrane are nearly the same as in the alimentary canal. In some cases the membrane is generally thickened, in others the thickening is confined to a circumscribed point, where it produces a projecting tumour or vegetation. Andral relates two cases in which the rima of the glottis was almost completely obstructed by whitish cauliflower vegetations of this description. Hypertrophy of the follicles with which the mucous membrane of the air-tubes is so thickly studded, has repeatedly been mistaken for tubercles, and also for the eruption of small-pox. M. Reynaud found the mucous membrane of the bronchi covered with villi in an individual who had laboured under chronic cough and dyspnoea for many years: as no villi are visible in the natural condition of this membrane, their appearance must be ascribed to the effects of hypertrophy. Hypertrophy of the mucous membrane of the minute bronchi, producing considerable diminution of their calibre, is a constant cause of dyspnoea, especially when situated at the orifices of the off-setting tubes. It is to this cause we must attribute the permanent sonorous and sibilous râles that are to be heard in the lungs of some asthmatics. In the genito-urinary organs the mucous membrane presents nearly the same changes from hypertrophy as those we have already described, namely, general thickening or enlargement of its mucous follicles, vegetations, excrescences, &c. These excrescences present considerable variety of texture, some of them consisting of a hard homogeneous tissue apparently destitute of vessels, others of a soft and highly vascular tissue, while others are formed by a mere prolongation of the natural membrane; so that this portion of the mucous membrane, like all others, presents two varieties of hypertrophy, one in which its substance is thickened but its texture not altered, and another in which its texture no longer retains its natural characters.* M. Louis found the mucous membrane of the bladder covered with villi in a patient who had been affected with hematuria for a number of years.† In this case also they must have been morbidly developed, as they do not exist in the natural state of the membrane, or, if present, are so minute as not to be perceptible.

Hypertrophy of the skin.—The cutaneous tissue, like the mucous, may be hypertrophied throughout its entire structure, or in some one or more of its component layers. Andral relates a very remarkable case of general hypertrophy of the skin occurring in an old woman who died of phthisis in the hospital of La Charité. She had formerly had an ulcer on her right leg, but for the last thirteen years the sore had been cicatrized, while the limb had gradually acquired an extraordinary development. On dissection the thickened integuments were found to consist of the following

layers: 1. the corium or cutis vera; 2. the papillary tissue, (*bourgeons sanguins* of M. Gautier); 3. over the papillæ three layers more or less distinct, according to the situation in which the examination was made. The first of these layers appeared like a delicate white line, which, as it dipped in between the papillæ, assumed an undulating appearance: this layer was analogous to that described by M. Dutrochet as the epidermic layer of the papillæ. Immediately over the undulating line just described, appeared another layer of a dark grey or brown colour; when sliced obliquely, it presented the appearance of a net-work formed by a number of delicate dark-coloured filaments crossing each other in every direction: this reticular layer was evidently analogous to the coloured layer in negroes. The third or most superficial layer presented a much greater degree of thickness and hardness than the preceding, and in some places exhibited a degree of consistence equal to that of horn: this layer exists only as a rudiment in man, but in animals is more perfectly developed for the production of the various species of shell and horn. 4. External to all these parts was situated the cuticle.*

Hypertrophy of the vascular system.—This may be considered as it affects the large blood-vessels, or as it is confined to the capillary system of vessels. The pregnant uterus affords an example of hypertrophy or preternatural development of all the bloodvessels which supply the organ; in like manner tumours and all morbid growths are accompanied with an increased development of the arteries and veins which supply them. It is not, however, always easy to determine whether this hypertrophy of the vascular system precedes or follows, is the cause or the effect of the increased growth of the solids. Dilatation of the aorta, especially at its arch, is often accompanied with considerable thickening of its parietes: in some cases this increased thickness is caused by the uniform hypertrophy of all the coats, in others the middle coat only is affected: when in this state, its natural organization becomes much more apparent; the yellow fibrous tissue of which it is composed becomes as evident in the human subject as it naturally is in the horse, but never presents any trace of muscular fibre even in the most extreme state of hypertrophy.†

The morbid alteration of structure described by authors under the name of *accidental erectile tissue*, is caused by hypertrophy of the capillary vessels of the part, which become increased both in size and number, and by being clustered and matted together like the vessels of the placenta,‡ form vascular patches or tumours of various shapes and sizes. In some cases these tumours are composed entirely of the capillary vessels in a state of hypertrophy; in others the tumours are com-

posed principally of other anatomical elements, such as excrescences from the mucous membrane, encephaloid tissue, &c. and the capillary vessels, though greatly increased both in size and number, form merely an accessory part of the structure of the morbid growth.—(See FUNGUS HÆMATODES.) M. Recamier states that the greater number of hemorrhoidal tumours are composed of the capillary vessels of the anus in a state of hypertrophy.*

Hypertrophy of the nervous tissue.—This has been observed in the brain, spinal marrow, and nerves. The anatomical characters of *hypertrophy of the brain*, as described by Dr. Dance in the fifth volume of the *Répertoire d'Anatomie*, &c. are the following: "The convolutions of the brain are compressed and flattened, the intervals between them disappear, and it seems as if the investing membranes of the brain had become too tight for it; the substance of the organ is firm, contains but little blood, and appears remarkably dry when cut into. The ventricles are almost entirely effaced, and the various surfaces of the brain deprived of their ordinary moisture." The affection generally involves both hemispheres, but is sometimes confined to one, or even to a part of one. Andral met an instance where the left thalamus opticus was one-fourth larger than the right, which was of its natural dimensions. Laennec mentions, in the second volume of the *Journal de Corvisart*, his having found the brain compressed and squeezed, as if the skull were too small to contain it, in different individuals whom he had supposed to be affected with hydrocephalus. In a memoir published in the *Revue Médicale* for December 1823, M. Meriadec Laennec has detailed several cases of this disease, from which he concludes that this change of structure is not excessively rare in its occurrence; that it is constantly accompanied with symptoms of epilepsy; that it develops itself with much greater rapidity than hypertrophy of any other organ, which he attributes to the organization of the texture in which it is seated; and, lastly, that the causes of the lead colic appear to have a very great influence in developing hypertrophy of the brain. In some cases the increased growth of the brain is so considerable as to produce an evident enlargement of the skull.

Dr. Elliotson relates the case of a lad who was remarkably precocious; his head was larger than the ordinary size of adults; he suddenly became apoplectic, hemiplegic, and died. On dissection the brain appeared much larger than it should be, and looked as if it had been ready to burst the skull asunder.† A similar case is recorded by M. Scoutetten, in the seventh volume of the *Archives de Médecine*: A child only five years old had an enormously large head, totally disproportioned to his age and size; his intellect was not in any way remarkable; his general health was good; and he died of an acute attack of

gastro-enteritis. On dissection, the dura mater was found firmly attached to the skull, and the brain filled the head so completely, that, on the roof of the skull being removed, it started out as if it had been relieved from considerable pressure: it was principally the superior and posterior parts of the hemisphere which had acquired this extraordinary development; for on making a perpendicular incision into the lateral ventricles, it was necessary to make a section three inches deep to reach them from above, while from below they were within an inch of the surface. It does not appear that this condition of the brain is constantly attended with any particular derangement of its functions; in the case related by M. Scoutetten, there were no symptoms of cerebral disease; in M. Laennec's cases the symptoms were those of hydrocephalus. In those detailed by his cousin M. Meriadec Laennec, the patients had paroxysms similar to those of epilepsy; and in the cases observed by Andral, the symptoms were in some instances analogous to those of epilepsy, and in others the individuals were suddenly seized with convulsions, in the midst of which they expired.*

Hypertrophy of the spinal marrow presents the following characters; its substance is remarkably firm, and so increased in size as to fill up completely the cavity of the vertebral canal.† Laennec found the spinal chord affected in this way throughout its entire length. Andral found the cervical portion of the chord hypertrophied in a child affected with epilepsy. Hutin,‡ Ucelli,§ and Ollivier, have likewise described this disease: respecting its pathology nothing certain is as yet known.

The nerves are also liable to an excessive development from hypertrophy. The ends of the nerves after amputation often become very large, and have their sensibility morbidly increased. Bichat describes this alteration as occurring frequently in the neighbourhood of organs affected with cancer. Gendrin found the nervus saphenus of three times its ordinary thickness, in the neighbourhood of a chronic ulcer on the leg of an old man. The same appearances have been also seen and described by Swan.||

A remarkable instance of hypertrophy affecting detached points along the course of the nerves, in a cretin, is recorded in the London Medical and Physical Journal for 1826. The inferior maxillary nerve presented several swellings as large as peas in all its branches, and the portio dura of the seventh, the eighth pair, and almost all the spinal nerves were similarly affected; the ganglions of the sympathetic were much larger than usual; that opposite the sixth vertebra was as large as a hen's egg flattened. This preternatural deve-

|| Observations on some Points relating to the Nervous System.

* Dictionnaire de Médecine.

† Medical Gazette, No. 217.

lopment of the ganglionic system has likewise been observed by other anatomists in cases of congenital idiocy.* Dr. Duncan found the abdominal portion of the sympathetic nerve increased to three or four times its natural size in a case of diabetes, and Lobstein found the supra-renal plexus greatly hypertrophied in a case of diseased supra-renal capsule. We have already stated, when speaking of hypertrophy of the vascular system, that in all cases of preternatural development or morbid growths, the bloodvessels which supply the part exhibit a proportionate increase of size; the nerves have not been observed to undergo a similar change. In hypertrophy of the nerves, it is important to distinguish whether the nervous pulp is affected, or merely its neurilema.

Hypertrophy of the fibrous tissue.—This is usually produced by irritation or chronic inflammation. This tissue has a remarkable tendency, when hypertrophied, to be transformed into fibro-cartilage, and to pass from thence by a second transformation into bone. These successive changes are frequently exemplified in the margins of the different orifices of the heart and in the valves, the thickening and subsequent ossification of which often arise from hypertrophy of the fibrous tissue, which enters in a rudimentary state into their anatomical structure.

Hypertrophy of bone.—The osseous system presents two forms of hypertrophy, according as its animal or calcareous substance is principally affected. In some cases both these alterations are combined. The bones are sometimes found uniformly enlarged throughout their entire structure, so as to attain in some instances to double their ordinary size and weight. This form of hypertrophy, which seems productive of no inconvenience during life, is seldom or never confined to a single bone, but affects the entire set, whether of the cranium, the thorax, the pelvis, or the upper or lower extremities; it is generally supposed to be congenital. Dr. Gall states that the skulls of idiots from birth are much thicker than those of other men,† and Lobstein remarks that the skulls of dwarfs are not only large in proportion to the other parts of the body, but that they actually exceed in size and weight the skulls of ordinary sized persons.‡ In rachitis the bones affected usually present an increase of size, accompanied with a diminution of weight and consistence, owing to hypertrophy of their animal substance, and the atrophy of their calcareous particles; but in some time after the rachitic affection has subsided, the bones usually attain a preternatural degree of density and strength. Mr. Stanley has observed that the copious deposition of calcareous matter, by which this change is affected, takes place principally at the inner side of the incurvated bone.§ In the disease

known by the name of *fragilitas ossium*, the atrophy of the animal substance, which is the immediate cause of the brittleness, is frequently accompanied with hypertrophy of the calcareous matter. The ivory-like induration, or *eburnation* as it has been termed, is most frequently met with in the flat bones of the cranium, and in the extremities of fractured bones between which a false joint has been established. A minor degree of condensation of the osseous structure is frequently caused by injury and inflammation of the part, or of its investing membrane, as in the union of fractures, &c. Dr. Gall preserved in his museum the skull of a soldier who received several severe blows on his head from the butt-end of a musket at the battle of Ohakow; he became delirious in consequence, and lived in that state for thirty years; the bones of his skull were exactly like ivory. Several anatomists have observed that the skulls of furious maniacs are remarkable for the extreme density and compactness of their texture: this alteration is in all probability connected with the irritation of their meningeal membranes. Nodes and exostoses are examples of local hypertrophy of the osseous system.

Hypertrophy of the lungs.—Laennec has remarked that when one of the lungs is destroyed, or from any cause rendered unfit for the performance of its functions, its fellow acquires a double energy, consequently an increase of nutrition, and after a certain time an augmentation of volume, and becomes at the same time firmer, more elastic, and compact. In place of collapsing when the chest is laid open, it sometimes protrudes from it, as if the space that contained it were too small. In instances of this sort it cannot be doubted that the air-cells are enlarged, and that their parietes have acquired a preternatural thickness, although it is extremely difficult to prove this even with the aid of the microscope. Hypertrophy of the lungs is sometimes formed in a very short space of time: in the case of a man who had pleurisy and consequent contraction of the chest, the opposite lung was found hypertrophied in the highest degree only six months after the commencement of the disease.*

Hypertrophy of the liver.—This gland is frequently affected with hypertrophy. In its natural state it is composed of two distinct substances; one reddish, formed chiefly by the minute ramifications of the capillary bloodvessels; the other white or yellowish, which seems chiefly destined for the secretion of bile; these two substances, together with their framework of cellular tissue, form the parenchyma of the liver, and the hypertrophy may be confined to either of these substances singly, or may affect them all conjointly. These different forms of hypertrophy produce several varieties in the colour, consistence, and form of the organ, which are usually attributed to the development of new morbid productions, such as scirrhus, cirrhosis, &c. There are two de-

‡ *Traité d'Anatomie Pathologique*.

§ *Medico-Chir. Trans.*, vol. vii.

* Laennec on Diseases of the Chest.

grees of hypertrophy of the white substance: in the first, the parenchyma of the organ is traversed by lines or circumvolutions of a yellowish white colour; in the second, both its interior and exterior are studded with numerous granules, either isolated or agglomerated, and remarkable for their colour, resembling that of yellow wax; these yellow granules, which are merely the white substance in a state of hypertrophy, Laennec regarded as an accidental tissue developed in the liver, and termed it cirrhosis, from its colour. This affection is described by Baillie as the *common tubercle* of the liver, and is generally known in this country by the name of the *drunkard's liver*. The red substance is likewise susceptible of a very remarkable kind of hypertrophy, which produces in the interior of the liver small hard red masses, distinguished from the surrounding parenchyma by their greater consistence and deeper colour. The cellular tissue of the liver is likewise liable to hypertrophy, in which case the organ loses its peculiar structure and organization, and large patches are found in it occupied only by cellular tissue in a state of hypertrophy. In all those cases the hypertrophy of one of the elementary tissues of the liver is accompanied with a corresponding degree of atrophy of the other tissues; but in some instances they all participate in the hypertrophy, and the parenchyma of the organ acquires an extraordinary development. This increased growth of the parenchymatous structure of the organ may take place in all the three lobes, or may be confined to one of them. Sometimes the right lobe is the one affected, and constitutes almost the entire organ, the left appearing like a small appendage attached to it; sometimes, again, it is the left lobe that is particularly enlarged, and the liver then projects considerably into the left hypochondrium, and, when felt through the abdominal parietes, might be taken for the spleen: in other cases the projection is observed only in the epigastrium, when it might be mistaken for a tumour of the stomach.* The causes that give rise to the different forms of hypertrophy of the liver are as yet unknown, it being a mere hypothesis to attribute them to inflammation; neither are we acquainted with any peculiar symptoms by which they may be detected or discriminated during the life of the individual from each other, or from other organic changes of that viscus. When the liver is much increased in size, its dimensions may be ascertained with tolerable accuracy by the extent of surface, which yields a dull sound on percussion.

Hypertrophy of the spleen.—The spleen is more frequently perhaps than any other organ enlarged beyond its natural dimensions: this increase of size, which is sometimes very considerable, is most commonly produced by the accumulation of blood within the splenic cells, but in some cases arises from a true hypertrophy of the parenchyma of the organ. When cut into, the natural structure seems to be pre-

served, except that it is much more solid and condensed than usual, and is intersected by a number of opaque white lines, formed by the hypertrophy of its septa. Dr. Baillie states, that though this may be looked upon as a monstrous growth of the spleen rather than as a disease, yet it may produce inconvenience by its pressure, and by altering in some degree the situation of the neighbouring viscera.*

Hypertrophy of the pancreas.—This gland is sometimes greatly hypertrophied, and as the cellular substance which intersects its substance participates in the affection, the viscus loses a good deal of its natural appearance, and is converted into a hard white mass, intersected by opaque membranous septa, not unlike scirrhus in other parts of the body.

Hypertrophy of the kidney.—The kidneys are sometimes found much larger than usual, without exhibiting any other change of structure; indeed, it generally happens that when one is incapable of performing its functions, either from original malformation or disease, the other, having double duty to perform, becomes preternaturally enlarged. Hypertrophy of the kidneys is said to be a frequent appearance in diabetes.† We have, however, seen several exceptions to this statement.

Hypertrophy of the lymphatic glands.—The lymphatic ganglions are frequently found in a state of chronic enlargement. We have seen the mesenteric glands in *tabes mesenterica* increased to four or five times their natural size, without presenting any appearance of degeneration or transformation of tissue. Cruikshanks mentions an instance in which the lymphatic glands in the neighbourhood of the bifurcation of the trachea were affected with this morbid change to such an extent as to cause fatal suffocation. In the internal iliac glands it is not uncommon, so as to form large indurated masses, and in the female may operate as a cause of difficult parturition, equally fatal to the mother and the child.‡

Hypertrophy of the thyroid.—Hypertrophy of the thyroid constitutes the disease known by the name of goitre or bronchocele, which is endemic in certain countries, and is generally supposed to depend on certain conditions of the air and water. (See BRONCHOCELE.)

Hypertrophy of the thymus.—It is by no means uncommon to find the *thymus* preternaturally developed in scrofulous or rachitic children. We have seen it so large in some cases as to cause an evident projection of the sternum.

Hypertrophy of the mammary glands.—The mammary glands are sometimes enormously developed. Dr. Joerdens relates an instance in which they grew to such a size as to reach down to the thighs.§

Enlargement of the prostate arising from an increased development of its natural structure is by no means uncommon at an advanced period of life: this affection may involve the

* Morbid Anatomy.

† Andral.

‡ Anatomy of the Absorbing Vessels.

§ Hufeland's Journal.

* Andral, op. cit.

entire gland, or may be confined to one of its sides, or to its middle lobe. Hypertrophy of the prostate causes considerable difficulty in voiding the urine by mechanically obstructing the neck of the bladder; it likewise occasions a difficulty in passing the fæces by its pressure on the rectum.

From the brief sketch we have drawn of some of the most remarkable effects of hypertrophy on the several tissues and organs in which it has been observed, it appears that this affection is one of extremely frequent occurrence, and productive of a great variety of morbid appearances which pathologists have only recently learned to refer to their true source.

If, from the consideration of the physical characters of this affection, we turn to the investigation of its immediate or proximate cause, we find that it consists in an excessive activity of the natural function of nutrition. In order to describe the mechanism of this excessive nutrition, it will be necessary to premise a few observations on the mode in which this process is accomplished in the natural or healthy state. The process of nutrition essentially consists in the several solids alternately receiving from and returning to the common nutritive fluid, the blood, a succession of particles similar to those of which their structure is naturally composed. The appropriation of the new particles is termed assimilation, and the detachment and removal of the old particles is known by the name of de-assimilation, or of interstitial absorption. Various opinions have been entertained by pathologists respecting the mechanism by which these changes are accomplished. According to Bichat, each organic tissue is supposed to have its appropriate exhalant arteries, from which it derives the materials requisite for its nutrition; these exhalents he supposes endowed with a peculiar sensibility, by virtue of which they are enabled to select from the blood and convey to their destination those precise ingredients which are fitted for the building up of the tissue or organ they supply: for example, he supposes that the bones possess a set of exhalant actions, which convey nothing but the calcareous phosphates; that the muscles have likewise a set of exhalents that convey only fibrine; and that there are likewise a particular set of nutritive exhalents for conveying albumen, gelatine, &c.: he likewise supposes the existence of a separate set of vessels for the removal of each of these substances. The existence of such a series of vessels has, however, never been demonstrated by dissection, and it is now generally believed that the elements of all the secretions are contained in the blood; that this fluid, holding all the different elements in solution, is conveyed by the capillary circulation to the intimate structure of the different solids, and that it is only by the plastic force inherent in the solids themselves that these elements are separated and applied to their destined purposes. According to this view of the subject, it is the several tissues themselves and the molecules of which they are composed that select their constituent in-

gredients from the blood, and appropriate them to their construction and support; and the power of assimilation is shared by every particle of every living solid in the body. This faculty of assimilation is compared by Lobstein to the action of a crystal, which when plunged in a saline solution attracts towards itself and promotes the crystallization of those saline particles homogeneous to itself, which were suspended in the fluid; so in like manner he conceives the organic molecule selects from the blood those elements which are homogeneous to it.*

In hypertrophy this assimilation or plastic force is preternaturally increased, and the consequence is that an excessive quantity of nutritious particles are assimilated, and the tissue or organ affected is over-nourished, that is, hypertrophied. Andral supposes that the same effect may be produced by a defect in the activity of the de-assimilating powers; that the absorbents do not carry away the materials they ought; and that in this way an accumulation of nutritious particles takes place independently of any increase in the assimilating powers of the part; and he adduces, in support of this hypothesis, the well known fact, that hypertrophies which have been combated in vain by bloodletting and emollient applications, often yield to the use of stimulants, such as iodine, mercury, &c. Again, the production of this alteration of structure has been by many pathologists attributed to an increased afflux of blood towards the part affected. This increased local determination of blood may readily be conceived to perform a very important part in the production of hypertrophy, but cannot be considered as its sole, or even as its most efficient cause; for it is evident that the increased determination of blood to an organ can of itself only produce the congestion of that organ, but can never cause its hypertrophy unless when aided by a corresponding increase in the assimilating powers of the part; and if we admit an increase of those powers, the other condition becomes unnecessary, for the increased powers of assimilation, by their more active appropriation of the nutritive particles contained in the ordinary supply of blood, are sufficient to produce the preternatural growth of hypertrophy of the heart, independently of any increase of the quantity of the nutritive fluid.†

Lastly, hypertrophy has been described by some authors as having an inflammatory origin; but this etiology of the affection, though correct in many instances, is inapplicable to many cases of excessive nutrition. In those unhealthy districts of the Alps, for instance, where bronchocele exists as an endemic disease, the individuals affected are for the most part sickly, pale, and exanguinous; there is no evidence in them of any inflammatory actions, either present or antecedent, and yet not only the thyroid, but the liver, the tongue, and the bones are often hypertrophied to an extreme

* *Traité d'Anatomie Pathologique.*

† *Andral, op. cit.*

degree in these cases: so also in scrofula and rachitis, the mesenteric glands, the upper lip, and the ends of the bones are often considerably enlarged, and yet such persons are not instances of increased vigour or of the inflammatory diathesis.

It is true that in many cases the first phenomenon which presents itself to our notice in the part where hypertrophy is subsequently to take place, is a degree of local irritation, attended with more or less of sanguineous congestion; but there are also many cases besides those we have specified where no symptoms of any such antecedent irritation can be observed. Indeed, as M. Andral remarks, its existence cannot always be fairly admitted either from analogy or induction; and even when present, it can only be regarded as giving rise to some derangement in the process of nutrition, but is altogether inadequate to account for the peculiar character of the alteration which ensues. In theory we have no reason to suppose that the hypertrophy or increased nutrition of an organ is necessarily preceded by inflammation, and in point of fact we ought not to admit a necessary connexion between these two orders of phenomena, since in many cases we find them existing singly, without the slightest proof of having been preceded or accompanied by the other.

In the present state of our pathological knowledge, it is perhaps premature to speculate on the proximate cause of hypertrophy, or to found our treatment exclusively on either of these theories: until we know how the process of nutrition is accomplished in health, it is idle to theorize on its accomplishment in disease. If we cannot comprehend how muscle or bone are formed from the blood in their due proportion, it need be no matter of surprise that we cannot explain how these substances are occasionally formed in excessive quantities. But though we cannot scrutinize the first causes of these processes, we may nevertheless observe the influence of circumstances in modifying their results, even though we cannot in all cases comprehend the precise mode of their operation. Thus, we learn from observation that the extirpation of the testes in the male, or of the ovaries in the female, has a marked tendency to produce an excessive development of the adipose tissue; in like manner we learn that a residence in certain countries causes hypertrophy of the thyroid; that syphilis produces nodes and exostoses; rachitis, enlargement of the ends of the bones; scrofula, of the lymphatic ganglions, &c.; and that irritation of the mucous membrane of the colon produces hypertrophy of the subjacent layer of cellular tissue, although the *modus operandi* of these causes is by no means equally obvious.

We would, therefore, recommend that the treatment of this affection should not be founded exclusively on either of the theories that have been formed respecting its proximate cause, but that the existence of hypertrophy being once ascertained, we should endeavour to discover, *experimentally*, what are the most efficient means of combating and subduing it.

By adopting this method of proceeding, iodine has been discovered to possess the power of dissipating hypertrophy of the thyroid, and mercury has been proved a no less powerful agent in removing certain forms of exostoses.*

The *exciting causes* of hypertrophy, so far as we are acquainted with them, may be divided into those which act through the medium of the constitution, and those which act locally. To the first class may be referred,—

1. That condition of climate or soil which renders bronchocele and cretinism endemic in certain districts of the globe. (See BRONCHOCLE.)

2. A peculiar idiosyncrasy or predisposition to the excessive development of the solids generally, or of certain tissues or organs in particular. This state of the constitution is remarkably exemplified in the disposition which certain individuals evince to accumulate fat under circumstances where others would almost die of inanition, as in the remarkable case of obesity related in a preceding part of this article. A still more remarkable case of general hypertrophy is recorded in the first volume of the *Journal Hebdomadaire*, p. 76. The individual was a strong healthy country girl, until, at the age of 18, the menstrual discharge ceased suddenly after exposure to a violent storm, and from that time she became subject to headach, numbness of the limbs, and shortness of breathing: these symptoms were attended with a gradual and progressive hypertrophy of her muscular, cutaneous, cellular, and adipose tissues, until at the end of eleven years after the suppression she presented the following appearances. Her height remained unaltered (five feet two inches); the skull was of the ordinary dimensions, but appeared exceedingly small in comparison to the face, which was enormously developed; the skin of the forehead, the eyelids; and eyebrows, nose, lips, cheeks, and chin, were of such a monstrous size as to suggest the idea of a mask meant for a giant at least eight feet in height. The tongue was so large as to fill the mouth almost completely; the neck could only be compared to that of the Farnese Hercules. The mammae were of an enormous size, and reached almost to the chin. The circumference of the trunk was equal to the height of the individual, but this prodigious size was not caused by the excessive accumulation of fat alone, as the muscles were every where largely developed, and appeared perfectly defined under the skin. The upper and lower extremities seemed disproportionately short on account of their enormous bulk, and the hands are represented to have been quite a curiosity for their size. The heart was hypertrophied in the same proportion as the other parts of the muscular system, and at each contraction struck the chest with such violence as to give the ear, when applied over it, a very smart blow. The brain likewise participated in the affection, and its faculties gradually merged into a state of idiocy. In this case, though the origin of the excess of nutrition may be traced to the sup-

* Andral, *op. cit.*

pression of the menstrual discharge, it is impossible to refuse admitting an idiosyncrasy on the part of the individual, as suppression of the catamenia is not necessary or even generally followed by any such alteration in the nutrition of the solids.

3. Syphilis and the abuse of mercury, which are known to produce hypertrophy of the osseous system in the form of nodes and exostoses.

4. Scrofula and rachitis, which have been observed to cause enlargement of the thymus, lips, and tongue, of the lymphatic and mesenteric ganglions, and of several parts of the osseous system, especially the ends of the long bones.

5. Full living and sedentary inactive habits, which usually dispose to excessive development of the adipose tissue.

Such are the principal general or constitutional causes of hypertrophy which observation has pointed out; but it must be confessed that the enumeration is by no means complete, and that the subject requires further investigation.

Among the principal local causes of hypertrophy may be enumerated the following:—

1. Irritation or inflammation, especially when it assumes a chronic character. We have already stated that this is by far the most frequent cause of hypertrophy. On referring to the descriptions we have given of this affection, it will be found that in a great majority of cases hypertrophy of the mucous, cutaneous, and cellular, as well as of the fibrous and osseous tissues, may be referred to this source. In such cases the hypertrophy is sometimes confined to the tissue which was previously in a state of irritation, while sometimes, after the tissue originally affected has returned to its natural healthy condition, the adjacent tissues retain a chronic form of disease, and fall into a state of hypertrophy.

2. Increased exercise of the functions of the affected organs. The agency of this cause in producing hypertrophy is most evident in the muscular and glandular system. It has been observed that persons who have lost the use of one arm or leg generally acquire an extraordinary degree of strength in the other, from the increased use that is made of it. In like manner, when one of the double organs, such as the kidneys or lungs, is rendered incapable of performing its functions with effect, the other, having double duty to perform, acquires a proportionate increase of development. Examples of hypertrophy of the muscular structure of the heart, bronchi, stomach, intestines, and bladder, arising from increased exercise of the fibres, have already been adduced.

Treatment of hypertrophy.—For all that is practically important respecting the treatment of hypertrophy, we must refer to the different articles in which the various species are noticed individually. We shall here content ourselves with a few general observations.

In the treatment of hypertrophy the first and most obvious indication is to remove, if possible, the exciting cause of the disease, as until that object is accomplished, our treatment can at best be but palliative, and in general, when the

cause which originally produced the hypertrophy is removed, the nutrition of the organ promptly returns to its natural standard: “*ab lata causa, tollitur effectus.*” As the alteration of nutrition is in most cases preceded or accompanied by evident symptoms of increased vascular action, the usual remedies for inflammation, viz., venesection, strict antiphlogistic regimen and perfect rest, are those most generally indicated; but we must not suppose that these remedies are equally applicable in every case, as the state of the constitution, and the circumstances under which the hypertrophy occurs, sometimes indicate a different or even opposite mode of treatment. When, for instance, the affection arises from scrofula, rachitis, or the residence in a country of cretins, the antiphlogistic regimen would only serve to aggravate the disease, and pure air and generous diet become in such cases the most valuable remedies. So, in like manner, when hypertrophy of one of the lungs or kidneys arises from increased action that is thrown on it by its fellow being incapacitated for performing its functions with effect, the diminution of its increased action, either by the exhibition of appropriate remedies, or, more effectually still, by restoring its fellow to the due discharge of its functions, will be found more efficacious in reducing the nutrition of the hypertrophied organ to its healthy standard than the most active depletory treatment. Again, it would be in vain to attempt combating by general or topical depletion the hypertrophied condition of the walls of the bladder so long as the presence of calculi in its interior kept up the irritation of its mucous membrane, and thereby maintained its muscular fibres in a state of frequent and violent action; for by such treatment we do not remove the cause of the disease, but only palliate its effects. Even this, however, becomes an object of considerable importance to the practitioner, when the cause of the hypertrophy is of such a nature as to baffle our attempts at its removal; as, for instance, in hypertrophy of the heart arising from organic disease of the valves.

There are but few medicines with which we are acquainted that possess any specific controul over this affection; of these the most effectual are iodine and mercury. The former has been found a specific in bronchocele, and has occasionally succeeded in dissipating enlargements of the lymphatic glands; and mercury has been found highly serviceable in removing enlargements of the bones, especially when proceeding from a syphilitic taint. When the hypertrophy arises from any of the constitutional causes we have enumerated, the treatment should be directed to the removal of that morbid state of the system on which it depends, and of which it is merely a symptom, and the tonic or antiphlogistic regimen prescribed according as the system requires to be invigorated or reduced. So, likewise, with respect to the topical treatment of this affection: when the part affected admits of such, the applications must be varied according as it exhibits excessive or deficient vascular action: in the first case

local abstraction of blood, fomentation and cataplasms may be applied, while in the second case stimulating applications and blisters will occasionally be found serviceable. It is impossible, therefore, to lay down any general plan of treatment universally applicable; each form of the disease must be treated with reference to its exciting cause, and more as the effect of a pre-existing disease than as a specific affection. In a general pathological article like the present, it would be foreign to our purpose to enter into a detailed account of the appropriate treatment of all the varied forms and different varieties of hypertrophy.

(R. Townsend.)

HYPERTROPHY OF THE HEART.—

In this article we purpose to develop, with as much brevity as the importance of the subject will allow, many of the leading principles common to organic diseases of the heart in general.

Hypertrophy of the heart is an augmentation of its muscular substance, resulting from increased nutrition. The terms *active* and *passive aneurism of the heart* we discard as vague and inaccurate, and adopt the following classification and nomenclature.

1. *Simple hypertrophy*, in which the walls are thickened, the cavity retaining its natural dimensions.

2. *Hypertrophy with dilatation*. This, the eccentric or aneurismal hypertrophy of Bertin, presents two varieties: viz.—

a. With the walls thickened and the cavity dilated.

b. With the walls of natural thickness and the cavity dilated: i. e. *hypertrophy by increased extent of the walls*.

3. *Hypertrophy with contraction*. In this, the concentric hypertrophy of Bertin, the walls are thickened and the cavity is diminished. This classification is no less convenient than conformable to nature. The form of the second variety was not known to Laennec, though it was to Bertin. That it *really* consists of an augmentation of muscular substance, and therefore constitutes hypertrophy, is too manifest to require comment; but a further proof than mere structure affords is that it sometimes produces the symptoms of hypertrophy,—a fact which the writer ascertained and made known several years ago, before he had any knowledge that M. Bertin had done the same.*

The terms “eccentric or aneurismal” and “concentric” are not so simple and expressive as hypertrophy with dilatation, introduced by Laennec, and its natural converse, hypertrophy with contraction. There is a further objection to the nomenclature of Bertin. His first variety of dilatation, identical in its nature with his second variety of hypertrophy, is designated by a totally different name, viz. *active aneurism* (Bertin, p. 376), which could scarcely fail to lead the inexperienced student into the erroneous idea that there was a difference in the nature of the two affections. Now the only

difference consists in degree—in a predominance of the one state over the other. The terms, therefore, should be such as distinctly to imply identity in nature, and difference in degree only; and this is done in the simplest manner by giving precedence to the word hypertrophy, or dilatation, according as the one affection or the other predominates. Thus hypertrophy with dilatation denotes a predominance of hypertrophy, while the converse, dilatation with thickening (see DILATATION), denotes a predominance of dilatation. Hypertrophy by increased extent (without altered thickness) of the walls,—the form *b.* of the second variety,—is thus designated when it is accompanied with the symptoms of hypertrophy; but it is called simple dilatation when the symptoms are those of dilatation.

We have thought it necessary to speak thus particularly on the subject of nomenclature, as up to the present moment it has created much confusion, and must continue to do so until the terms active and passive aneurism are forgotten.

Anatomical characters of hypertrophy of the heart.—Before describing the anatomical characters of hypertrophy of the heart, it is necessary to give the reader an idea of the natural dimensions of the organ. Unfortunately, it is impossible to determine these exactly; for as they vary according to age, sex, and other circumstances, there is no immutable standard of comparison which might serve as a criterion. It is only by the eye, therefore, (and an experienced eye is necessary for the purpose,) that it can be determined whether the proportion of the heart to the system, and of its several parts to each other, is natural. The proportions assigned by Laennec approach perhaps as near the truth as it is possible to arrive: they are as follows. “The heart, comprising the auricles, ought to have a size equal to, a little less, or a very little larger than the fist of the subject. The walls of the left ventricle ought to have a thickness a little more than double that of the walls of the right: they ought not to collapse when an incision is made into the cavity. The right ventricle, a little larger than the left, and having larger columnæ carneæ, notwithstanding the inferior thickness of its walls, ought to collapse after an incision has been made into it. Reason indicates and observation proves that in a sound and well built subject the four cavities of the heart are, within very little, equal to each other. But as the walls of the auricles are very thin, and those of the ventricles have considerable thickness, it results that the auricles form scarcely a third of the total volume of the organ, or the half of that of the ventricles.” In the fœtus and very young children, the thickness of the left ventricle does not exceed that of the right to the extent described. The right cavities are rather larger than the left, and this is not owing to sanguineous distention attendant on dissolution; for the disparity is found, though in a less degree, in animals destroyed by hemorrhage.

The muscular substance in hypertrophy is

* Vide an Essay by the writer in 1824, read to the Royal Med. Soc. Ed.

usually firmer and redder than natural. These characters, however, are not essential to the disease; and when they exist in a great degree, they constitute induration, a distinct affection, dependent, not on increased, but rather on altered nutrition of the part.

Hypertrophy may be confined to a single cavity, or it may affect several, and even the whole simultaneously; and sometimes one cavity is thickened while another is attenuated. The reasons of this will be explained when we come to treat of the exciting causes. When all the cavities are hypertrophous, and at the same time dilated, the heart attains a volume, two, three, and occasionally even four times greater than natural; its form, instead of being oblong, is spherical; its apex is scarcely distinguishable; and as the diaphragm does not retire sufficiently to yield space downwards for the enlarged organ, it assumes an unnaturally horizontal position, encroaching so far upon the left cavity of the chest, as sometimes to force the lung upwards as high as the level of the fourth rib, or even higher. When great enlargement is accompanied by adhesion of the pericardium, the organ is secured by the attachments of the membrane in a higher situation than its gravity would otherwise dispose it to assume; and being thus impacted between the spine and the anterior parietes of the chest, it is apt to occasion a preternatural prominence of the præcordial region. We are not aware that this remark has been made by any other writer, but we have seen the phenomenon in so many instances, that we are disposed to assume it as a general fact. (See PERICARDITIS.)

The left ventricle, being more prone to thickening, and not less to dilatation than the right, sometimes attains a volume seldom or never acquired by the right; and when its enlargement is enormous, it occupies not only the left præcordial region, but extends far under the sternum, where its impulse and sound may be mistaken for those of the right ventricle.*

The walls of the left ventricle, the natural thickness of which averages about half an inch in the adult, may be increased to the extent of one, one and a half, or, according to some, of two inches. The cases are rare in which it exceeds an inch and a quarter. The situation of the greatest thickening is usually a little above the middle of the ventricle, where the columnæ carneæ take their origin. Thence, the thickness decreases rather suddenly towards the aortic orifice, and gradually towards the apex, where it is reduced to less than half. When hypertrophy maintains these proportions in the different parts of the ventricle, the state is only an exaggeration of the natural form. The case is different when the hypertrophy takes place inwards and diminishes the cavity; for then the whole ventricle is nearly equally thickened, and it is usually globular and firm.

The columnæ carneæ generally participate in

hypertrophy, but sometimes, when there is much co-existent dilatation, they appear to be stretched, flattened, and attenuated. The inter-ventricular septum, though belonging almost entirely to the left ventricle, is commonly less thickened than the external walls of this cavity. When the left ventricle is greatly enlarged, the right, if unchanged, is applied in a flattened form to its superior and lateral part, and by contrast looks singularly small. But if, as generally happens, the right is elongated, it is, as it were, folded around the left.

When the right ventricle alone is hypertrophous, it may descend lower than the left, and constitute the apex of the heart. Its columnæ carneæ, naturally more numerous and interwoven than those of the left, are more susceptible of thickening than the walls themselves. Hence the increased size of the columnæ is commonly the first object that arrests the attention, and to them alone is the hypertrophy in many instances confined. They are sometimes so curiously interlaced and attached as to traverse the ventricle in every direction, subdivide it into various compartments, and in some cases almost totally to fill up its cavity: (as in case 89 by Bertin, and that of Collins, p. 469 of Treatise of Dr. Hope.) These changes never take place to the same extent in the left ventricle. The total thickness of the walls of the right ventricle, naturally averaging three lines, rarely exceeds four or five; yet it has been known to attain from eleven to sixteen, as appears from the 88th case of Bertin, and one, by Soins, in the *Archives de Médecine*. In a girl of nine years old we have met with it measuring six or seven lines, which is equal in proportion to nearly double that extent in the adult. Hypertrophy without dilatation is much more rare in the right than in the left ventricle. The greatest thickening of the right ventricle is near its base; towards the apex, though the columnæ carneæ be enlarged, their interstices are usually thin, and not unfrequently translucent.

Hypertrophy may not only be confined to a single ventricle, whether the right or the left, but it may be limited to particular parts only, as the base, the septum, the apex, the columnæ carneæ, or the external walls; the remainder of the cavity being either natural or attenuated. Again, a thickened ventricle may be contracted in one part, while it is dilated in another. In examining the dead subject in mixed cases, it is necessary to counterpoise the opposite conditions, to balance the hypertrophy against the attenuation, and the dilatation against the contraction, in order to determine which is the predominant affection.

The hypertrophy of the auricles is almost invariably of the second species, or that with dilatation. Laennec even states that he has never met with any other.* The simple and the contracted forms, however, are not without example. The thickening is diffused in a very uniform manner throughout the cavities, the muscoli pectinati being the only parts in which

* Laennec, tom ii. p. 507. Treatise on Dis. of Heart, by Dr. Hope: case of Lambert.

* De l'Auscult. tom. ii. p. 524.

it is more considerable than elsewhere; and as they are larger and more numerous in the right than in the left auricle, it is in the former that hypertrophy proceeds to the greatest extent. It occasionally renders the auricle nearly as thick as the right ventricle. This we have never known to take place in the left auricle. Sometimes the muscoli pectinati are the only parts in which hypertrophy shows itself. The thickening of the auricular walls seldom exceeds double the natural state, and being even then inconsiderable, it may easily be overlooked by an inexperienced eye. When it amounts to a quarter of an inch, which is rarely the case, it is very perceptible.

Mode of formation and predisposing causes of hypertrophy.—Hypertrophy takes place in the heart by the same process as in any other muscle. Increased action causes an augmented afflux of blood, and there results a corresponding increase of nutrition. Diminished action, on the contrary, has the reverse effect. Thus, the arms of the smith and the legs of the dancer are usually robust; while limbs paralysed or not exercised are pale and emaciated. If, however, the circulation can be re-invigorated in the palsied part, nutrition is increased.

In the same way, when from mechanical obstruction or any other cause blood is inordinately accumulated in the heart,—short, however, of that degree which would paralyse its remittent power—the organ is provoked to extraordinary efforts; it struggles against the obstacle; it frets and labours to overcome it; the coronary arteries are excited to increased activity; augmented nutrition ensues; the parietes are thickened, the muscular power is increased; the effects, superadded to the cause, induce a still greater violence of action; and thus the disease is not only established, but has a constant tendency to increase.

The left ventricle is much more prone to hypertrophy than the right; and the right, again, than the auricles. This admits of explanation on very simple principles. It is found that hollow muscles resist over-distention by their contents with a force exactly proportionate to their strength. Thus, if we suppose two cavities, one twice the strength of the other, and add to the natural pressure on those cavities such a surplus as will exactly overpower the weaker, this surplus will bring into action only one half of the supplementary strength of the more vigorous. Now, as the act of resistance, by stimulating the arteries to increased action, is the cause of increased nutrition, it follows that stronger muscles must be the more susceptible of hypertrophy. Accordingly, on referring to the heart, we find that the relative structure of its several compartments is such as to predispose the organ to those changes which it actually undergoes from over-distention. The left ventricle, being charged with the immense burden of the greater circulation, is proportionably substantial and robust; the right, having the comparatively light task of propelling the blood through the minor or

pulmonary system, is little more than one-third as thick and powerful as the left: the auricles, again, having a still less laborious function to perform, have a still more limited muscular provision. Hence, it is easily understood how a given increase of distending force, sufficient to overcome the contractile and elastic power of the right ventricle, might operate merely as a stimulus to the superior muscularity of the left. While the former, therefore, incapable of reacting on its contents, would dilate, the latter, excited to extraordinary efforts, would become hypertrophous.

It is not however to be supposed, that while the left ventricle is becoming hypertrophous, it may not at the same time undergo dilatation; nor, on the other hand, that the right ventricle, while yielding to dilatation, may not become hypertrophous; for observation teaches us that the combination of hypertrophy with dilatation, either in the left ventricle alone, or in the two conjointly, is the most ordinary form of organic disease of the heart.

For an explanation of the cause why dilatation accompanies hypertrophy, the reader may refer to the article on DILATATION. Why hypertrophy sometimes accompanies dilatation of the right ventricle may be here explained, and it admits of an explanation in one or other of two ways. 1. It has been remarked by Laennec (*Traité*, tom. ii. p. 496,) that a large proportion of mankind are born with ill proportioned hearts, the parietes being a little too thin or a little too thick on one or both sides. Now when this abnormal thickness exists in the right ventricle, it is clear, from what has been said above, that it must impart to that ventricle an increased disposition to hypertrophy. This explanation, however, is not satisfactory, as the existence of the malformation described by Laennec cannot be positively proved: still, as all the other organs and parts of the body are liable to defects of natural conformation, it is consistent with analogy to suppose that the heart may be liable to them also.

2. As augmented nutrition is excited in the left ventricle by stimulating it in proportion to and not beyond its power, so a stimulus bearing the same proportion to the power of the right ventricle, must have the same effect on it also. Accordingly, in the majority of cases of hypertrophy of the right ventricle, an obstacle is found to exist of such a nature as to stimulate it in the manner described. The obstacles which we have most frequently found to produce the effect, are, contraction of the mitral valve operating in a retrograde direction through the lungs, and that of the semilunar valves of the pulmonary artery. These affections being usually slight at their commencement and slow in their progress, oppose an obstacle to the circulation not only moderate in degree, but constant in its operation,—the two circumstances best calculated to induce hypertrophy of the right ventricle.

M. Bertin conceives that the greater tendency of the left ventricle than of the right to hypertrophy, depends upon the more stimulant quality of the arterial blood circulating through

the former. This opinion he founds on the circumstance that hypertrophy of the right ventricle in most cases accompanies patescence of the foramen ovale, which lesion he thinks causes an influx of arterial blood into the right ventricle. But, admitting that arterial blood in the right ventricle does occasion hypertrophy, it does not follow that it should have the same effect on the left; for of the former ventricle it is a morbid stimulus, but of the latter it is the natural one. Accordingly, direct proof is to be found in the auricles, that arterial blood is not the cause of hypertrophy; for the left auricle, which on M. Bertin's principle ought to be more subject to hypertrophy than the right, is less so. It will be shown, moreover, in the article on malformations of the heart, that, in the cases on which M. Bertin founds his opinion, the blood does not enter the right ventricle.

Exciting causes.—According to the foregoing opinions on the mode of formation of hypertrophy, it will be apparent that every circumstance capable of increasing the action of the heart for a sufficient length of time,—a period which must be very considerable,—may be a cause of hypertrophy. These circumstances may be either, 1. of a nervous, or 2. of a mechanical nature. 1. The former class comprises all moral affections and all derangements of the nervous function that excite long continued palpitation. To these we would add protracted rheumatic fevers; for we have known these give rise to hypertrophy, though there was apparently no inflammation of the heart or its membranes. 2. The latter class embraces all physical causes which can either *accelerate* or *obstruct* the circulation, and thus occasion a preternatural pressure of the blood upon the heart. The physical causes which *accelerate* the circulation, are, violent and protracted corporeal efforts of every description. In growing youths, excessive rowing is one of the most efficient. We have met with several in which it has produced the effect. The physical causes which *obstruct* the circulation are very numerous. They comprise smallness of the aorta, whether congenital or acquired; dilatation of the aorta; inequalities of its internal surface; all diseases of the valves of the heart which either contract their apertures or impede their movements; adhesion of the pericardium; all affections of the chest that obstruct the circulation through the lungs, as peripneumony, acute or chronic; empyema; hydrothorax; chronic catarrh; emphysema; phthisis,* narrowness of the chest, either con-

genital, or occasioned by curvature* of the spine, &c.; encroachment of the diaphragm on the cavity of the chest from the pressure of tight stays, of the gravid uterus, of abdominal dropsy, aneurism, &c.

In reference both to the nervous and the physical causes of palpitation, it may be said that young persons of a plethoric habit and sanguine temperament are the most susceptible of their influence. Hence it is that very stout and high-coloured females, from the age of seventeen to twenty-five, are peculiarly subject to hypertrophy. We have noticed this fact more especially in servants coming to London from the country.

Order of succession in which the several compartments of the heart are rendered hypertrophous by an obstacle before them in the course of the circulation.—As an obstacle to the circulation operates on the heart in a retrograde direction, the cavity situated immediately behind it is the first to suffer from its influence. Accordingly all the impediments seated in the aorta, its mouth, or the arterial system, act primarily on the left ventricle, which, being likewise exposed to the heaviest burden when the circulation is accelerated, has to conflict against a greater variety of exciting causes of hypertrophy than any other cavity of the heart. On this account, therefore, as well as from the thickness of its parietes, it is subject to hypertrophy in a greater degree than any other.

So long as the left ventricle is capable of propelling its contents, the corresponding auricle, being protected by its valve, remains secure. Hence, in a large majority of cases, the auricle is perfectly exempt from disease, while the ventricle is even enormously thickened and dilated. But when the distending pressure of the blood preponderates over the power of the ventricle, its contents, not being duly expelled, constitute an obstacle to the transmission of the auricular blood. Hence the auricle becomes over-distended, and the obstruction may be propagated backwards through the lungs to the right side of the heart, and there occasion the same series of phenomena. When the obstruction thus becomes universal, as is frequently the case, it may happen either that all the cavities are thickened, or those only which from their conformation have the greatest predisposition to it.

When the mitral orifice is contracted, especially if the aperture be very small, the left ventricle, being insufficiently supplied with blood, is not stimulated to its ordinary contractile action, and consequently becomes emaciated and occasionally flaccid or softened. Meanwhile, the left auricle, having to struggle against the contracted valve in front, and also to sustain the distending pressure of the blood flowing in from the lungs, invariably becomes thickened and dilated. The engorgement, extending backwards through the lungs to the right ventricle, occasions its hypertrophy and

* We have not found that phthisis is so decided a cause of disease of the heart as we should be led to suppose from the extreme pulmonary obstruction to which it sometimes gives rise. The reason of this appears to be, that, in the early stages, when the disorganization is not extensive, the circulation is little embarrassed; and in the advanced stages, the mass of circulating fluids is so much diminished in consequence of deficient nutrition and augmented cutaneous transpiration, that the heart sustains little additional burden from the obstruction in the lungs. In most cases, however, the right ventricle is found somewhat dilated,—a remark which has been made more especially by M. Louis and Dr. Williams.

* The majority of hump-backed persons are ultimately attacked by disease of the heart.

dilatation; under which circumstances, namely, hypertrophy of the right ventricle and contraction of the mitral valve, the lungs suffer in a pre-eminent degree; for being exposed to the augmented impulsive power of the right ventricle behind, and incapable of unloading themselves on account of the straitened orifice in front, their delicate and ill-supported vessels are strained beyond the power of resistance. If, therefore, they cannot disgorge themselves sufficiently by a copious secretion of watery mucus, they effuse blood by transudation into the air-vesicles and tubes, and form the disease denominated *pulmonary apoplexy*. We have found this affection to occur more frequently under the circumstances described than under any other.

When the mitral orifice is permanently patulous, so that, at each ventricular contraction, blood regurgitates into the auricle, this cavity suffers in a remarkable degree; for it is not only gorged with the blood which it cannot transmit, but, in addition, sustains the pressure of the ventricular contraction. Permanent patulency of the mitral orifice, therefore, constitutes an obstruction on the left side of the heart, and the effect of this, as of contraction of the orifice, may be propagated backwards to the right side.

When the impediment to the circulation is primitively seated in the lungs, the right ventricle, situated immediately behind them, is the first to experience its influence; and when the cavity is so far overpowered by the distending pressure of the blood as to be incapable of adequately expelling its contents, the obstruction extends to the auricle; the process being exactly the same as that already described in reference to the left ventricle and auricle.

Obstruction in the right auricle, whether from this or any other cause, presents an obstacle to the return of the venous blood, and therefore ultimately causes retardation throughout the whole venous system. Nor is this all; for the retardation is propagated through the capillaries to the arterial system, and thus at length returns in a circle to the heart. In this way is explained what at first sight appears an anomaly; namely, that the left cavities are sometimes rendered hypertrophous by an obstruction situated behind them in the course of the circulation. The left ventricle, for instance, may be rendered hypertrophous by a contraction of the mitral orifice.

The reader must here be again reminded that the exciting causes of hypertrophy are equally those of dilatation; and that, supposing no unknown agencies to interfere, as may sometimes possibly happen, it depends on the proportion which the exciting cause bears to the reacting energy of the cavity exposed to its influence, whether that cavity become affected with hypertrophy, with dilatation, or with a combination of the two.

It may be said, generally, that when congestion is *constant* in a cavity, dilatation is more commonly the result; and that when there is only resistance to the expulsion of the blood, without constant engorgement of the

cavity, it is more common for hypertrophy to be produced. Contraction, for instance, of the aortic orifice causes hypertrophy of the left ventricle in a greater degree than dilatation; whereas patulency of that orifice, attended with regurgitation and constant engorgement of the cavity, causes dilatation in a greater degree than hypertrophy.

Hypertrophy with contraction most commonly proceeds from straitening of an orifice. Thus the greatest hypertrophy with contraction of the right ventricle upon record was accompanied with straitening of the pulmonary orifice to two lines and a half in diameter. (Case 87 by M. Bertin.) We have met with a very similar case; and several connected with malformation of the heart are on record.

It may be useful to subjoin a list of the various forms and combinations of hypertrophy and dilatation, and to shew the comparative frequency of their occurrence. On the latter point we shall offer the result of our own observation, and we believe that they correspond very closely with those of others.

The diseases are of more frequent occurrence in proportion as they are higher in the following scale.

1. Hypertrophy, with dilatation of the left ventricle, and a less degree of the same in the right.
2. Hypertrophy with dilatation of one ventricle, especially the left, with simple dilatation of the other.
3. Simple dilatation of both ventricles.
4. Simple hypertrophy of the left, and hypertrophy with dilatation of the right.
5. Dilatation with attenuation of the left.
6. Hypertrophy with contraction of the left.
7. Hypertrophy with contraction of the right.

Of the auricles.—1. Distention, particularly of the right, from congestion during the act of dissolution.

2. Dilatation with hypertrophy.

3. Simple hypertrophy.

4. Hypertrophy with contraction.

Pathological effects of hypertrophy, and mode of their production.—M. Laennec supposes the general symptoms of all organic diseases of the heart to be nearly the same.* It may be said without prejudice to one who has done so much, that, on this subject, both he and all the authors who preceded him have entertained inaccurate ideas. They had studied these diseases in the aspect under which they most commonly present themselves, namely, complicated one with another; and it is unquestionable that when so viewed, they display a general similarity in their symptoms. But it had never occurred to those authors to analyse each disease in an isolated form. When so examined, although certain symptoms are common to all, they severally manifest differences of a striking kind, obviously dependent on their respective organic peculiarities, and which may, therefore, be fairly regarded as the essential and diagnostic characters of each.

* De l'Auscult. tom. ii. p. 487.

M. Bertin has the merit of having been the first to display in a clear light the essential pathology of hypertrophy. His distinguished talent for generalization, however, has, we believe it will be allowed, carried him too far. He contends that authors are wrong in having assigned to hypertrophy or *active aneurism* as its symptoms, dyspnoea, suffocation, violet injection of the face, engorgement of the lips and of the venous capillaries in general, passive hemorrhages, and serous infiltration. He contends that these are the signs, not of hypertrophy, but of some co-existent lesion, as a contracted orifice or any other affection capable of obstructing the circulation; and that pure uncomplicated hypertrophy is characterised by signs of increased activity and energy of the circulation, instead of by dropsy and the other signs of retardation of the blood.

That this is true in reference to the *pure uncomplicated* form of the disease, before embarrassment of the capillary circulation has taken place, will not be denied by any one who has had opportunities of verifying the symptoms by dissection. But M. Bertin is not, in our opinion, supported by sound observation when he says that serous infiltration and the whole class of symptoms bespeaking an obstructed circulation, are totally foreign and repugnant to hypertrophy. The truth we believe to be, that the very same energy of the circulation which gives rise to active hemorrhages, apoplexy, &c., causes, as its next effect, engorgement of the arterial capillary system; the necessary consequence of which is serous infiltration, and more or less of all the other symptoms indicative of retardation of the blood.

M. Bertin is of opinion that the impediment to the respiration which attends enormous enlargement of the heart, results from the encroachment of the organ on the lungs. This, however, is disproved by the fact that tumours of a much larger size, as for instance, aneurisms of the aorta, malignant tumours, &c. have existed in the chest, even for years, without producing similar inconvenience.

The primary effect of universal obstruction of the lungs by engorgement resulting from hypertrophy of the heart, is, to produce oedema of their cellular tissue and dyspnoea. The secondary effect is, to gorge the right side of the heart, and thus impede the return of the venous blood from the system at large; which impediment co-operates with the increased energy of the arterial circulation in producing anasarca.

Hypertrophy, however, does not produce serous infiltration so readily and promptly as a direct, primary obstacle to the return of the venous blood,—a fact which admits of a rational and obvious explanation. When there is an obstacle to the return of the venous blood, suppose, for instance, contraction of the tricuspid orifice, two causes conspire to produce the capillary congestion; namely, the direct pressure of the arterial vis-a-tergo, and the retrograde pressure of the retarded venous

blood. But when the latter pressure does not exist, when the veins freely receive and transmit their natural proportion of blood, the force of the arterial circulation must be *very greatly* increased, before it can so far overcome the elasticity of the capillaries as to give rise to engorgement and infiltration.

This satisfactorily accounts for the difference in the history and character of infiltration as resulting, on the one hand, from pure hypertrophy, and on the other, from contraction of a valve or other primary obstacle to the circulation. In the former case, it appears late, is generally moderate in extent, and requires for its production an aggravated form of hypertrophy; in the latter case, it appears comparatively early, is more copious, and yields with less facility to remedies.

The same reasons that account for the tardy occurrence of dropsy in pure hypertrophy, account, likewise, for another characteristic of this malady when moderate in degree; namely, the slight and transitory nature of the attacks of dyspnoea. For if the quantity of blood impelled into the lungs by the right ventricle, and the force with which it is impelled, are not very excessive, the pulmonary veins are capable of relieving the engorgement almost as quickly as it takes place: consequently the hurry of the respiration subsides promptly after the removal of its exciting cause; in other words, as soon as the action of the heart becomes a little calm. The sum, then, of all that has been said, is, that pure hypertrophy gives rise to increased force and activity of the circulation, and that, when this force surmounts the natural tonic power of the capillaries, congestion, infiltration, and the other phenomena of an obstructed circulation, ensue.

To these principles an exception presents itself in hypertrophy with contraction, whenever the cavity of the ventricle is too small to be capable of transmitting the natural quantity of blood. In this case, supposing the left ventricle to be the one affected, the arterial circulation sustains a diminution of force and activity; and whether the one ventricle or the other be affected, the disease creates an obstruction tantamount to that produced by valvular contraction: on the same principles, therefore, it generates dropsy and the other phenomena of a retarded circulation.

The effects of hypertrophy of the left ventricle on the brain are so pre-eminently important, that it is necessary to advert particularly to this subject, for the purpose of bringing it prominently into view. Since the researches of the present day have demonstrated that even a slight thickening of the walls of the heart constitutes a morbid state, and have unfolded to view the connexion subsisting between that state and a train of symptoms formerly either wholly overlooked or attributed to other causes, instances of apoplexy supervening upon hypertrophy have been so frequently noticed, that the relation of the two as cause and effect is one of the best established doctrines of modern pathology. Eight or nine cases of suddenly fatal apoplexy, and numerous cases of palsy,

from hypertrophy, have, within a few years, fallen under our own observation. In the majority of them the patient exhibited what is commonly called the "apoplectic constitution;" that is, a robust conformation, a plethoric habit, and a florid complexion: in others these characters were absent; but the total number of the cases of apoplexy from hypertrophy is much greater than we have witnessed, during the same period, of apoplexy from causes independent of hypertrophy; whence we are led to believe, with MM. Richerand and Bertin, that hypertrophy forms a stronger predisposition to apoplexy than the apoplectic constitution itself; and that, in most instances, those persons who present the apoplectic constitution in conjunction with symptoms of increased determination to the head, are, at the same time, affected with hypertrophy.

Nor is it to apoplexy alone, but to cerebral inflammations and irritations of every description, and even to inflammatory action in general, that hypertrophy of the left ventricle gives a tendency. The history of individuals affected with it frequently presents a striking narrative of violent headaches, brain fevers, various inflammatory complaints, and states of great nervous irritability and excitation. As the ophthalmic artery is derived from the carotid within the cranium, the eye participates with the brain in the effects of hypertrophy, and is vascular, brilliant, and very prone to ophthalmia. The wasting away of the eye which Professor Testa has remarked as one of the effects of disease of the heart, is, with good reason, supposed by M. Bertin to be connected with ossification of the ophthalmic arteries, a frequent concomitant of hypertrophy of the left ventricle.

The shock of an hypertrophous left ventricle may to a certain extent be intercepted, and its effects on the brain counteracted, by contraction of the aortic orifice. A patient was under the care of Mr. Babington, at St. George's Hospital, Sept. 16, 1829, for a surgical complaint, in whom the walls of the left ventricle were an inch thick, without any change of the cavity; and the aortic and mitral orifices were respectively encircled by a ring of bone as thick as a writing quill. The two valves, though overspread with calcareous scales, were capable of discharging their functions. Notwithstanding this extraordinary state of disease, the patient had attained the age of eighty without manifesting symptoms of diseased heart sufficient to arrest his own attention or that of his medical attendants. His advanced age, indeed, proves that they could not have existed in any considerable degree. In this case, therefore, the valvular contraction appears to have been exactly sufficient to counteract the hypertrophy, and maintain the circulation in a state of equilibrium. The generality of authors, however, have greatly over-rated the power of contraction of the aortic orifice to counteract the effects of hypertrophy on the brain. They have supposed that a moderate and even a slight degree of contraction is sufficient for the purpose.

There can be no greater error; and it is one into which they could not have fallen, had they been aware that an inconsiderable degree of contraction has very little effect in diminishing the strength, tension, and regularity of the pulse, as is shewn in the article on valvular disease.

To have demonstrated the influence of hypertrophy of the left ventricle on the brain, is equivalent to having showed that of the right ventricle on the lungs. For, in the same way that the brain receives *directly* the shock of the blood which the left ventricle shoots into the aorta, so the lungs receive *immediately* the impulse communicated to the column of blood, which the right ventricle propels into the pulmonary artery. Consequently, when the walls of this ventricle are augmented in thickness and energy, they impart a corresponding activity to the pulmonary circulation, and sometimes overcome the tonic power of the vessels. Hence ensues hemorrhage, or what was called by Laennec pulmonary apoplexy, from its taking place by the same mechanism as apoplexy properly so called, in cases of hypertrophy of the left ventricle. The hemoptysis resulting from this cause consists of fluid, red blood, and is generally copious, sudden, and productive of febrile excitement of the circulation. It is, in short, an active, arterial hemorrhage, and essentially different from that passive species, hereafter to be described, which results from retardation of the blood in the venous capillaries of the lungs. (See PULMONARY APOPLEXY and HEMOPTYSIS.)

Diagnosis of hypertrophy.—The signs of hypertrophy are of two classes: 1. *general*; 2. *physical*. According to our experience, neither of these classes, taken separately, is sufficient to indicate any disease of the heart with perfect certainty: taken conjointly, they render the diagnosis so easy that a material error can scarcely be committed.

I. *GENERAL SIGNS.*—In describing these we shall follow the course of the circulation; commencing, after having noticed the action of the heart, with the circulation through the lungs, proceeding to that through the aortic system, and concluding with that through the veins.

The description of symptoms which we are about to offer, refers, it must be distinctly understood, to simple hypertrophy, unless when it is otherwise stated: the symptoms of *hypertrophy with dilatation*, which will be noticed in passing, are only an aggravated degree of the same—as the reader will sufficiently understand, if duly acquainted with the foregoing principles relative to the formation and effects of these diseases. When the dilatation predominates over the hypertrophy, the symptoms of course approximate more nearly to those of dilatation.* The symptoms of *hypertrophy with contraction* will also be noticed incidentally with those of simple hypertrophy.

Palpitation.—By this is to be understood a

* Vid. DILATATION OF THE HEART.

morbidly increased action of the heart, both as to strength and frequency. As the hypertrophous heart acts with an energy which, even in its tranquil state, verges on palpitation, and which, under the slightest excitement, actually amounts to it, the patient experiences this symptom more unintermittingly than in any other disease of the organ. It is induced by stimulants of any description: as muscular efforts, particularly that of ascending; mental emotion; flatulence; acidity or bile; spirituous or highly seasoned ingesta, and sometimes by a full meal of any kind. The violence of the attack generally subsides promptly after the operation of the exciting cause has been suspended, and little remains but a slight sense of pulsation in the præcordial region. In the advanced stage, however, of hypertrophy, and still more of this conjoined with dilatation, when the circulation has become embarrassed, the paroxysms are sometimes very severe and prolonged, though they never attain that fearful extreme of violence and obstinacy which is witnessed in cases complicated with valvular or aortic obstruction, or adhesion of the pericardium.

Dyspnœa.—While the enlargement of the heart is moderate, the patient, during a tranquil state of the circulation, feels little or no difficulty of respiration; but he is incapable of making the same corporeal efforts as other persons without losing breath: to use a common phrase, he is "short-winded." After a respite of a few minutes, however, he recovers, and is, therefore, seldom deterred by this symptom from prosecuting his accustomed avocations. We have frequently observed that individuals who pant on first setting out on a walk, are capable of sustaining great exertions without inconvenience when they get warm and the blood is freely determined to the surface. When the disease has proceeded so far as to occasion dropsy, more or less dyspnœa becomes habitual, and it sometimes occurs, conjoined with palpitation, in paroxysms of excessive severity. From this period, indeed, the symptoms are a compound of those of hypertrophy and those of an obstructed circulation, the latter of which are more particularly considered in the article DILATATION. Hypertrophy with contraction, as already stated, is sometimes accompanied with symptoms of an obstructed circulation.

Cough.—There is generally little or no cough in the early stages, but it always supervenes when dropsy appears, in connection with which more or less sanguineous and serous congestion almost invariably takes place in the lungs, and gives rise to the symptom in question. When the hypertrophy is confined to the left ventricle, the cough is milder and later in its appearance than when the right ventricle is affected. We have seen a dry, hacking and wheezing cough amongst the earliest symptoms in young and plethoric females, whom it attacks in paroxysms after any over-exertion, as ascending a stair. It is often also very troublesome on first rising in the morning.

Hemoptysis.—This may occur at any period of the disease, and the hemorrhage, being active

—the result of a too impetuous discharge of blood into the capillary system—is generally sudden and copious, consists of fluid arterial blood, and is attended with febrile excitement.

Pulse.—The pulse in hypertrophy of the left ventricle undergoes, from valvular and other lesions, a variety of modifications which disguise its real nature. It must, therefore, be studied in cases totally exempt from complication. In such it is almost invariably regular, and bears strict relations in strength and size to the thickness and capacity of the left ventricle. Thus, in simple hypertrophy it is stronger, fuller, and more tense than natural: it swells gradually and powerfully, expands largely, dwells long under the finger, and is sometimes accompanied with a thrill or vibration. These characters are still more marked in hypertrophy with dilatation, so long as the hypertrophy is predominant; but when the dilatation has proceeded so far as to diminish the contractile power of the muscular fibres, the pulse, though still full and sustained, is soft and compressible. In hypertrophy with contraction of the cavity, it is strong, hard, and tense, but small and cord-like, expanding little under the finger. The action of the carotids corresponds with that of the radials, and they may generally be seen to pulsate from the sternum to the angle of the jaw. In the temporals also a sense of throbbing is usually experienced.

Affections of the head.—The patient complains of a "rushing of blood to the head" on making any corporeal effort or stooping; of intense throbbing and lancinating headaches, aggravated by the recumbent position, and especially by the act either of suddenly lying down or rising up; he complains also of vertigo, tinnitus aurium, scintillations and other visual illusions; and sometimes of a lethargic somnolency, which so completely subdues the faculties both of the mind and the body, as utterly to incapacitate him for every species of exertion. These symptoms, if not relieved, terminate in palsy or apoplexy. From this catastrophe the patient is often preserved by the opportune occurrence of epistaxis, to which, happily, he is peculiarly liable. From the circulation in hypertrophy being active in the eye, this organ is bright and sparkling, and sometimes vascular or blood-shot.

Complexion.—The effect of hypertrophy is to heighten the colour so long as the capillary circulation continues unembarrassed, but afterwards to diminish and change it. Every individual, however, does not acquire a florid colour. Whether he acquire it or not, depends, in truth, upon the original complexion, the series of changes being different in those who are naturally florid, and those who are pale—a fact not generally known. In the former, the colour becomes remarkably vivid, and being generally accompanied with plethoric turgescence, it gives the aspect of health and good condition. But when the capillary circulation begins to labour, the red changes into a purplish patch on the cheeks, the nose and lips become more or less purple, violet, or livid, and the intermediate skin becomes sallow

and cachectic. In great hypertrophy with dilatation the purple and violet colours are sometimes of the deepest dye. In those who are naturally devoid of colour, hypertrophy either does not excite it at all, or merely increases in a slight degree the general vascularity of the face. This vanishes entirely when the capillaries become obstructed, and is superseded by universal cadaverous paleness, extending sometimes even to the lips. They, however, are generally somewhat livid.

Serous infiltration.—This, for reasons already assigned, seldom appears before the hypertrophy is very considerable or becomes conjoined with dilatation. It frequently shews itself first in the face; a circumstance attributable to the great number and size of the cerebral arteries, and to the force with which the blood is injected into them in consequence of their proximity to the heart. With the dropsy supervene, to a greater or less degree, all the other symptoms of an obstructed circulation.

Signs of hypertrophy of the right ventricle.—Hypertrophy of the right ventricle produces, according to Corvisart, a greater difficulty of respiration and a deeper colour of the face than is produced by the same affection in the left ventricle. Another sign is, the more frequent expectoration of pure arterial blood.

Turgescence of the external jugular veins accompanied by pulsation synchronous with that of the arteries, was pointed out by Lancisi as a sign of "aneurism," i. e. *hypertrophy with dilatation*, of the right ventricle; and we have rarely known it absent in this affection. Of such cases, therefore, we regard it as one of the best general signs. Venous pulsation is not, in our opinion, attributable to regurgitation through the tricuspid valve, as Bertin supposes; in substantiation of which opinion we may say that regurgitation would be attended with a bellows or other such sound: this sound, however, is not found to be a concomitant of jugular pulsation. Is the rationale of the phenomenon as follows? namely, as the ventricle, when hypertrophous, contracts with augmented power, the recoil of the tricuspid valve is preternaturally impetuous: hence, the column of blood in the act of descending into the ventricle is repelled with such an increase of force, that its impulse is propagated as far back as the jugular veins. This effect would be more considerable when the orifice and valve are enlarged, as is usually the case in hypertrophy with dilatation, because the quantity of fluid repelled would be greater. The effect would also be favored by congestion of the great veins, (a state which generally accompanies hypertrophy with dilatation of the right ventricle,) because, when congested, they are more tense unyielding tubes, and transmit an impulse more readily.

The jugular pulsation is double: a weaker pulsation precedes that occasioned by the ventricular systole. The weaker is occasioned by the auricular systole, and the mechanism of its formation we conceive to be this: at the time that the auricle contracts, the ventricle is in a state of moderate or natural fullness; it

therefore offers a certain degree of resistance to the ingress of more blood from the auricle; consequently, so much of the blood compressed by the auricular systole as cannot get forward into the ventricle, is forced back into the veins and causes their pulsation.

A difficulty has sometimes been experienced in distinguishing jugular pulsation from that of the carotid arteries; an error which may easily be avoided by observing that the jugular pulsation is confined to the lower part of the neck, and is far on the humeral side of the carotid. The pulsations of the artery, on the contrary, extend as high as the angle of the jaw, and in the direction of the anterior margin of the sterno-cleido mastoideus muscle.

The jugular turgescence, again, disappears in some degree during inspiration, and reappears on expiration; which movements, therefore, must not be confounded with the pulsations answering to the systole of the ventricle.

General signs of hypertrophy of the auricles.—There are none that are distinguishable from those of disease or obstruction in the corresponding ventricle or orifice, to which the hypertrophy of the auricles owes its origin. The detection of hypertrophy of the auricles is of little importance, the cause that produced it being the source of danger.

II. PHYSICAL SIGNS.—*Impulse.*—In simple hypertrophy, the impulse communicated by the stethoscope while the patient is in a calm state, is usually so strong as distinctly to raise the head of the observer, and sometimes even sufficient to produce a shock disagreeable to the ear. The greater the hypertrophy, the longer this heaving takes for its performance. When the malady exists in a great degree, we evidently perceive that the heaving takes place with a gradual progression; it seems as though the heart swelled and applied itself to the parietes of the chest, at first by a single point, then by its whole surface, and finally sank back in a sudden manner. This sinking back, which we have been in the habit of designating by the term *back-stroke*, is occasioned by the diastole of the ventricles, during which action the heart sinks back from the walls of the chest with a force greater in proportion to its thickness and capacity. Accordingly, the *back-stroke* is strongest in hypertrophy with dilatation, but it may also be very considerable in simple hypertrophy. In the healthy heart it is not perceptible, neither is it in dilatation without hypertrophy.

A strong, slowly heaving impulse, then, is the principal sign of simple hypertrophy; and the affection may be known to be greater when the impulse is followed by a back-stroke. Both these signs exist in hypertrophy with contraction, but in a less degree, and the back-stroke may be absent if the disease is not great.

In simple hypertrophy and that with contraction, the impulse is seldom perceptible much beyond the præcordial region, except during attacks of palpitation.

In hypertrophy with dilatation the signs are a compound of those of hypertrophy and those of dilatation. The contraction of the ventricles

can easily be felt by the hand applied to the præcordial region, and we find, especially during palpitation, smart, violent shocks, which strongly repel the hand. If we attentively examine the patient, even when most calm, we see that his head, his limbs, and even the bedclothes, are strongly shaken at each contraction of the heart. The pulsations of the carotids, the radials, and the other superficial arteries are often visible. The impulse of the heart can sometimes be distinctly felt under the clavicles and on the left side of the thorax; sometimes even in the back, especially in meagre subjects and children.

In hypertrophy with a predominance of dilatation, the pulse is ordinarily not considerable; but it becomes very marked during palpitation, especially if accompanied with fever, and it has a very different character from that occasioned by simple hypertrophy. The beats are strong, hard, and produce a shock analogous to the blow of a hammer; but the blow seems to strike a small space; it expends itself as it were on the thoracic parietes, and does not communicate to the head of the auscultator a heaving proportioned to its force: it differs, in short, from the impulse occasioned by great hypertrophy, in the circumstance that, in the latter, the ventricles in a distended state seem to heave with their whole length against the thoracic parietes, which yield to the effort; while, in the former case, the point only of the heart seems to strike the parietes with a sharp, smart, accurately circumscribed blow, only capable of producing a sort of concussion rather than a real heaving. The same species of impulse takes place in purely nervous palpitations, in reference to which we have called it *jerking*.

When the impulse is increased on one side only of the præcordial region, that is, under the inferior part of the sternum for the right side, and between the cartilages of the fifth and seventh left ribs for the left, we infer that the corresponding ventricle only is affected; and when it is increased on both sides, we conclude that both are affected, which is more commonly the case.

In hypertrophy, and hypertrophy with dilatation, independent of valvular disease, the beats of the heart even during palpitation are rarely irregular, unless when they become enfeebled by excessive dyspnoea or by failure of the vital powers on the approach of dissolution.

The impulse of the heart is diminished by loss of blood, diarrhoea, any exhausting disease, rigid and long continued abstinence, and, in general, by all the causes capable of producing debility. Consequently, a moderate hypertrophy might, without due care, be overlooked in a patient under any of these circumstances.

The impulse of the heart, moreover, may, even in cases of marked hypertrophy, cease entirely when there supervenes intense dyspnoea, connected with some affection of the lungs, especially peripneumony, pleurisy, œdema of the lungs, asthma, and the pulmonary congestions which form during the last moments of life. The sounds likewise diminish, or even entirely cease: no inferences, therefore, should

be drawn from an exploration made under such circumstances.

Sounds.—Hypertrophy has the effect of deadening the sounds of the heart. In simple hypertrophy, the first sound, i. e. that produced by the ventricular contraction, is duller and more prolonged than natural in proportion as the hypertrophy is more considerable, and it generally terminates in the second sound without any interval. When the hypertrophy exists in an extreme degree, the first sound becomes nearly and sometimes wholly extinct. The second sound, i. e. that produced by the ventricular diastole, is very brief and dull, and in extreme cases scarcely perceptible. The interval of repose is shorter than natural, in consequence of the first sound being longer. Both sounds are proportionably weaker when the ventricle is contracted as well as hypertrophous. In most cases of this description the sounds can scarcely be heard under the left clavicle and at the upper part of the sternum. Sometimes they cannot be heard farther than the impulse can be felt; that is to say, scarcely beyond the limits of the præcordial region.

Each sound of the heart, though essentially one, consists of the sounds of the two sides united. This is proved by a bellows murmur in the left præcordial region being audible in the right, and vice versâ. It does not follow, therefore, that because one ventricle is hypertrophous, the sound of the heart in general should be very limited in its range; for that of the other will be heard over an extent proportioned to its intensity, though not quite so far as when strengthened by its fellow. On the other hand, a morbidly increased sound of one ventricle, as by dilatation or a bellows-murmur, will be heard *alone* at points beyond the range of the natural sound of the other or healthy ventricle. Accordingly, it is only in hypertrophy of both ventricles that we must expect to find the sounds confined within very narrow limits.

We have not been able to verify the remark of Laennec, that “in hypertrophy, often when a strong heaving, without any first sound, is felt in the præcordial region, and the second sound can scarcely be distinguished, the latter is heard alone under the clavicles, and even on the back; and in less severe cases of this kind it is always heard more distinctly in these places than in the præcordial region, especially in meagre and narrow-chested persons.” We cannot understand on what principle it could be so, even supposing the auricular contraction were, as he imagines, the cause of the second sound; for as both the right auricle and ventricle are in immediate proximity and partly in contact with the sternum, it is inconceivable how the sound of either should be less distinct not an inch from its source than at a remote point. We have, however, found Laennec’s remark true when the sound was drowned in the præcordial region by a bellows-murmur or pulmonary râle; the explanation of which is, that the second sound, being of a more acute nature than the murmurs, is more readily transmitted to a distance.

On the same principle also, is to be ex-

plained another doctrine of Laennec, the accuracy of which we have frequently verified: namely, that "in healthy subjects, but in whom the heart has rather thin walls, the second sound is sometimes stronger under the clavicles than the first, although the same difference is not observable in the præcordial region." The reason of this is, that the second sound, being more acute, is more easily propagated.

In hypertrophy with dilatation the sounds are increased. The first is, as it were, a compound of the sound of dilatation and that of hypertrophy: namely, from dilatation it derives a loud, abrupt, or flapping commencement, and from hypertrophy a prolonged termination, like a respiratory murmur. The second sound, though not in general changed in its character, is louder than natural. These sounds may frequently be heard over the whole chest, both posteriorly and anteriorly, especially in children and meagre subjects.

In hypertrophy with dilatation the sound of the ventricular contraction is sometimes accompanied with a bellows murmur. This we have found to be almost always the case when the heart is extremely large and contracting with vehemence. The sounds of the heart, in every form of hypertrophy, may be diminished by the same causes that diminish the impulse.

Resonance* of the præcordial region on percussion is defective in simple hypertrophy, provided the heart be considerably enlarged; but, as hypertrophy and dilatation is the disease in which the organ attains the greatest volume, it is that in which resonance is most frequently and most extensively defective. In all cases of considerable enlargement the dulness as well as the impulse are lower down than natural, except in adhesion of the pericardium, by which affection the heart is more or less braced up.

Progress and termination of hypertrophy.—Hypertrophy, while moderate, and not complicated with any mechanical impediment to the circulation, is productive of very little inconvenience. This is especially true with respect to children. In them the heart is naturally larger in proportion than in adults; and in many this amounts to a very considerable degree of hypertrophy with dilatation, accompanied with greatly increased impulse and sound; yet the general symptoms manifested by such are often scarcely appreciable, and the increased action itself subsides towards the period of puberty by the establishment of a more correct proportion and equilibrium between the heart and the system.

At the adult age also, and during the whole period of manhood, an individual of an otherwise sound and vigorous constitution may be affected with hypertrophy to a moderate extent, without experiencing any sensible deterioration of the general health (with the exception of being more liable than others to cerebral and phlogistic affections), or any diminution of muscular force and activity; and if his habits with respect to diet and exercise be moderate, he

may pass a long series of years, and even attain the extreme period of senility, without being conscious that he is the subject of organic disease. The only general signs denoting the existence of the malady will be, perhaps, a little shortness of breath on exertion, and occasional feelings of slight palpitation. Amongst the labouring classes these symptoms, even in a considerable degree, are so little regarded that their presence is often disavowed by the patient, though palpably manifest to the physician. If, however, an individual affected with hypertrophy abandon himself to intemperate living, or engage in occupations requiring great corporeal exertion, he rarely fails to bring on either apoplexy, palsy, hemoptysis, or an irremediably aggravated state of the disease, which embitters and curtails his existence.

The celerity with which these accidents are induced depends on circumstances. In general, the progress of hypertrophy is very slow and gradual, but in some cases it is rapid: in several instances we have known it terminate fatally within a year from its commencement. The circumstances occasioning these variations are connected with—1, the form of the disease; 2, its complications; 3, the nature and intensity of the external exciting causes; and, 4, the constitution of the patient. It is of the utmost importance that the practitioner be able to form some estimate of the influence of these circumstances; for it is by this means only that he can foresee the course of the disease, and direct his treatment with judgment and decision. It may be useful, therefore, to enlarge a little on this subject.

1. The progress and termination of hypertrophy are influenced by the form of the disease. *Simple hypertrophy* is more apt than any other form to induce apoplexy while the patient is apparently in perfect health. This is to be accounted for by its tendency to create plethora, while at the same time it does not incapacitate the patient for active corporeal exercise and the pleasures of the table. When premature death does not occur from apoplexy or hemoptysis, simple uncomplicated hypertrophy runs a more chronic course than any other form of the disease.

Hypertrophy with dilatation, especially if great, is a far more harassing, dangerous, and, if we may be allowed the term, *acute* affection than the preceding. All its symptoms are more violent, and its course is more rapid. It is somewhat less apt to occasion unexpected attacks of apoplexy; probably because the greater dyspnoea which it occasions deters the patient from violent exercise and high living. When once the palpitation and dyspnoea have attained such an extent as *imperatively* to demand periodical bleedings at brief intervals, the malady hurries with an uninterrupted course to its fatal termination.

2. The progress and termination of hypertrophy are influenced by its complications. When hypertrophy is connected with contraction of an orifice or any other obstacle to the course of the blood, the symptoms are greatly aggravated. For, first, in consequence of that

* See much valuable information on this subject in the "Procédé Opératoire" of M. Piorri, Paris, 1830, p. 112, et seq.

obstacle, the hypertrophy proceeds to a greater extent; and, secondly, the violent struggles of the heart to surmount the obstacle subvert the general balance of the circulation. To speak more explicitly, suppose the obstacle to be situated in the aortic orifice. While the left ventricle is palpitating to disgorge itself through the contracted aperture, the right, acting in concert with it, deluges the lungs with an inordinate quantity of blood; whence ensues a paroxysm of dyspnoea: next, in consequence of the pressure of blood through the lungs, the supply to the left ventricle is increased. This ventricle, therefore, instead of relieving its engorgement by palpitation, only aggravates it, and the fit does not subside until either the heart becomes gradually exhausted by its own efforts, or (what is more common) until the internal congestion is relieved by determination to the surface or a copious discharge of watery mucus from the lungs. The most violent, though perhaps not the most distressing, paroxysms of palpitation and dyspnoea that we have witnessed have occurred in the particular complication described. In others there may exist a greater feeling of suffocation (the source of the greatest distress), as will hereafter be explained in the articles VALVES, DISEASES OF THE, and POLYPI.

Adhesion of the pericardium, which rarely fails to produce hypertrophy with dilatation, is an extremely formidable complication of this malady. It greatly aggravates all the symptoms, and accelerates the fatal event, which not unfrequently takes place within the period of a year; and we have known it occur in nine months.

Febrile or inflammatory complaints supervening on an advanced degree of hypertrophy exasperate the malady in a surprising manner, so as not unfrequently to carry off the patient in the course of a few days. The effect seems to be produced by the febrile excitement keeping up, as it were, a perpetual fit of palpitation and embarrassment of the circulation, which the constitution cannot support beyond a brief period. Peripneumony has pre-eminently this effect; apparently because it not only excites the heart, but obstructs the circulation through the lungs.

3. The progress and termination of hypertrophy are influenced by the nature and intensity of the external exciting causes.

The principal of these are, over-exertion, excesses at table, and mental perturbation, the latter of which, though not strictly external, may be ranged under this head. The effect of these requires no explanation, but it may be said that the dangerous influence of over-eating is greatest in simple hypertrophy, because it generates plethora and increases the tendency to apoplexy; while over-exercise and intemperance are more prejudicial in hypertrophy with dilatation, because they increase the dilatation, which is the more dangerous part of the disease.

4. The progress and termination of hypertrophy are influenced in a remarkable degree by the constitution of the patient. The robust

resist its encroachments much longer than those who are delicate and effeminate: and if the former, either from bad air or want of exercise, from disease, or from age, become unhealthy, emaciated, and feeble, they are rendered much more susceptible of the effects of the disease. This (if we may indulge in a mere speculation) is possibly in consequence of emaciation taking place to a greater extent in the muscular and adipose tissues than in the internal viscera, whence, the latter becoming predominant in size, the equilibrium between the heart and the system is subverted. This is exactly the converse of what occurs at the period of puberty in those who had laboured under enlargement of the heart when children, for in them the equilibrium is restored by the system enlarging with the growth in proportion to the size of the heart.

Prognosis.—The general prognosis is favourable in the early and unfavourable in the advanced stages of the disease. The particular prognosis must be founded on an estimate of the various circumstances of the case formed according to the above rules.

Treatment of hypertrophy.—As it is easier to diminish the nutrition of the heart than to increase it, or to remove a valvular or other mechanical obstruction, it is very conceivable that hypertrophy is more susceptible of cure than any other organic affection of the heart.

In the treatment the first care should be to remove any known exciting cause of the malady. It is equally obvious that as this malady consists in an increased power and action of the heart, bloodletting and other reducing and tranquillizing means are the appropriate remedies. Laennec strongly recommends that they be employed with courage and perseverance on the plan of Albertini and Valsalva. We cannot say that our own observation leads us to coincide entirely in this opinion. We shall first, therefore, give a sketch of the treatment alluded to, the sanction accorded to which by names of the highest authority renders it at least deserving of the most attentive consideration; and shall afterwards point out in what respects it appears to us to be objectionable.

This treatment, according to M. Laennec, ought to be prosecuted in an energetic manner, especially in the commencements; and in aiming to enfeeble the patient, we ought much more to fear resting short of the mark than exceeding it. We should commence by abstracting blood as copiously as the patient can support without falling into a state of sinking; and we should repeat the operation every two, four, or eight days, until the palpitations have ceased, and the heart no longer gives, under the stethoscope, more than a moderate impulse. We should, at the same time, reduce to at least one half the quantity of aliments which the patient ordinarily takes, and diminish even this quantity if he preserve more muscular strength than suffices to take, step by step, a walk of a few minutes in the garden. In a stout adult Laennec usually reduces the quantity of aliments to fourteen ounces a day, amongst which he thinks there should be only two ounces of white animal food. If the patient wishes to

take broth or milk, he counts four ounces of these liquids for one of animal food. Wine ought to be interdicted. When the patient has been about two months without experiencing palpitation, and without strong impulse of the heart, we may dispense with the bleedings, and somewhat diminish the severity of the regimen, if habit has not yet been able in any degree to reconcile him to it. But it is necessary to revert to the same means, and with equal rigour, if in the sequel the impulse of the heart increase again. We ought not to have confidence in the cure until the expiration of a year of complete absence of all the symptoms, and especially of all the physical signs of hypertrophy. We must be afraid of allowing ourselves to be deceived by the perfect calm which bloodletting and abstinence sometimes very promptly produces, especially if we have commenced the treatment at a period when the hypertrophy was already accompanied with extreme dyspnoea, with anasarca, and with other symptoms which gave reason to fear an approaching death.

If we begin the treatment of hypertrophy of the heart at a period when it has already produced severe effects, particularly anasarca, ascites, œdema of the lungs, and a very marked state of cachexy, we ought not on that account to shrink from bleeding and abstinence. To obtain success, it is necessary, according to the same author, that the physician and the patient arm themselves with almost equal patience and firmness; for it is not more difficult for the latter to resign himself to perpetual fast and frequent bloodlettings, than for the former to struggle daily against the opposition of relations, friends, and the discouragement which cannot fail to seize upon the patient in a treatment which ought to continue at least several months, and sometimes to be prolonged during several consecutive years.

Such is the manner in which M. Laennec employs the treatment of Albertini and Valsalva; and he states that he could cite a dozen instances of cures of hypertrophy, either simple or with dilatation, which have not been falsified for several years. One important case which he details, seems to prove that the treatment causes atrophy of the heart; for the organ was remarkably less than the fist of the subject, and was shrivelled or wrinkled in a longitudinal direction.

Our objections to the treatment described are founded on the circumstance that, though we have invariably found the greatest benefit to be derived from sparing abstractions of blood at intervals of two or three weeks or more, we have constantly noticed that when from the severity of the dyspnoea and palpitation in the advanced stages of the complaint, the practitioner was induced, or thought himself compelled, to resort to frequent bleedings at short intervals, the patient, though perhaps momentarily relieved, progressively declined from that moment, the paroxysms recurring more frequently and with greater violence, until they eventually terminated in his destruction. Now, on comparing a patient under these circum-

stances with one under the influence of mere reaction from loss of blood, the analogy appears to us to be very intimate. In both, the violence of the heart's action, so far from being repressed by a reiteration of the bloodletting, is only increased: in both the blood is, and necessarily must be, attenuated and deteriorated in consequence of the fibrinous portion and red globules being replaced to a greater extent than natural by serum, which is more expeditiously regenerated.

These, then, are apparently the causes of the patient's decline. The prejudicial effects of the reaction are sufficiently obvious; and the state of the blood not only contributes in all probability to the reaction,* but, by its deteriorated quality, is unsuitable for the due nutrition and conservation of the system.†

It would appear, therefore, that the indications in the treatment of hypertrophy are, to diminish the quantity without materially deteriorating the quality of the blood, and to do this in such a manner as, without producing reaction, permanently to enfeeble the action of the heart and the energy of the circulation. The safest and most effectual means of fulfilling these indications have appeared to us to be the following:

Four, six, or eight ounces of blood should be taken every two, three, four, or six weeks, according to the strength of the patient, and sufficient to keep down palpitation, dyspnoea, and strong impulse of the heart. If the head be much affected, the blood should be drawn by cupping from the nape of the neck. The diet should consist of white animal food and liquids in small quantity, unless, from the advanced state of the disease, the blood be so impoverished as to be insufficient for the maintenance of the system, when a more nutritious though still spare diet may be allowed. Every thing stimulating, as spirituous and fermented liquors, and highly seasoned dishes, should be avoided. Any exercise taken should be so gentle as never to hurry, and, if possible, never even in the slightest degree to accelerate the circulation. When the action of the heart appears to increase, and yet general bleeding is not expedient, three or four copious and watery alvine evacuations should be procured daily by saline aperients, of which none answers better than one or two drachms of sulphate of magnesia in infusion of roses twice or thrice a-day. This may be continued for a week or ten days according to the effect; and either the same or some analogous aperients should be employed habitually in sufficient doses to keep

* Vid. Treatise on Dis. of the Heart, by the writer, p. 75.

† It does not follow that though the treatment of Albertini and Valsalva be unsuitable for hypertrophy, it is equally so for aneurism of the aorta; as in the latter the object is to produce a sudden and extreme, though temporary reduction of the force of the circulation, in order to promote the formation of fibrinous coagula in the sac: an expedient which is sometimes perfectly successful in effecting a cure of aneurism, but which will not have the same effect on hypertrophy.

the body gently open, and to procure, if possible, liquid evacuations. When salines are used habitually, their debilitating effects on the intestinal canal may be in a great measure counteracted by adding to the infusion of roses an equal quantity of comp. infus. of orange-peel, and six or eight minims of diluted sulphuric acid.

In addition to purgatives we have seen the most decided advantage result from diuretics; and not only when there was dropsy, but equally when there was none. Their mode of operation appears to be ultimately the same as that of purgatives; namely, they drain off the serous portion of the blood. We have found many patients, conscious of the benefit which they derived from this class of remedies, to be in the constant habit of taking cream of tartar, broom-tea, and other similar popular medicines. One patient affected with contraction of the mitral valve to the size of an ordinary pea, by these means warded off dropsy, beyond the slightest oedema of the feet, for ten years. When decided dropsy appears, it must be combated by the most efficient diuretics—the supertartrate, tartrate, acetate and nitrate of potass, squill, digitalis, spirit of nitric ether, decoction of broom, &c., with mercury if not contra-indicated. As no class of remedies is more variable and uncertain than this, when one fails another should be resorted to; and it not unfrequently happens that a weaker is more successful than a stronger. Should diuretics wholly fail, hydragogue purgatives, as elaterium, tincture of jalap, infusion of senna with tartrate of potass, &c. are often invaluable substitutes.

The state of the stomach and of the biliary secretion should never be overlooked in hypertrophy, as their derangements are amongst the most efficient exciting causes of palpitation. The remedies suitable for dyspepsia and bile are therefore to be resorted to. We deem it unnecessary here to enlarge on them, and on the treatment of dropsy, cough, dyspnoea, &c. as these subjects will be found fully discussed in the article VALVES, DISEASES OF THE.

It frequently happens that, notwithstanding the most judicious use of the remedies mentioned, the irritability of the nervous system frustrates their tendency to reduce and tranquillize the action of the heart. In this case sedatives are eminently useful, and the best effects often result from tincture of digitalis, to the extent of *mx* or *xxx* twice or thrice a-day; from two or three drops of hydrocyanic acid, administered as often; from three or four or more of extr. of hyoscyamus or conium once or twice a-day; and from half a grain of acetate of morphia twice a-day.

The above, and indeed every other mode of treatment is unavailing if not *steadily* pursued, and it must be pursued for one, two, three, or more years. Thus employed, we have found it effect cures in a considerable number of instances, some of which were advanced even to the second degree. In the first degree, especially before the period of puberty, this fortunate event is often obtained although bleeding be

resorted to only at long intervals, as of from six weeks to three months.

(J. Hope.)

HYPOCHONDRIASIS.—1. *Definition and characteristic of the disease.*—Hypochondriasis, or the hypochondriac malady, is a disease in which symptoms of dyspepsia, such as flatulence, eructation, with a sense of uneasiness in the stomach and hypochondria, are combined with a remarkable lowness of spirits or a desponding habit of mind, and a constant disposition to attend to every minute change in the bodily feelings, and to apprehend extreme danger from the most trifling ailments. The last-mentioned feature in the complaint has been particularly selected and strongly described by the nosological writers. “Desperant ægri de suâ valetudine recuperandâ ob ructus, borborrygmus, palpitationes, tremorem præcordiorum, fugaces vertigines, flatulentiam. Hinc persuasi fatum lethale sibi imminere, omnia symptomata et minimas mutationes in corpore suo scrupulosè observant, narrant et describunt medicis, suisque querelis alios mox et alios defatigant, ingenio cæterum et appetitu pollentes.”* By some writers hypochondriasis has been regarded as a mere variety or accidental modification of dyspepsia. Nearly in this light it appears to have been considered by Hoffmann, who wrote an able but somewhat prolix treatise “de malo hypochondriaco.”† He termed it “a spasmodico-flatulent affection of the primæ viæ, namely, of the stomach and intestines, arising from a disturbed and inverted peristaltic action, by sympathy throwing the whole nervous system into commotion, and deranging all the functions of the animal economy.” Sydenham in his celebrated treatise on hysteric diseases identifies those disorders with hypochondriasis. He says that the most peculiar symptom is the “making large quantities of urine as clear as rock-water.” This, on “diligent inquiry, he found to be the distinguishing sign of those disorders, which we call hypochondriacal in men and hysteric in women.” Hoffmann strenuously opposed this doctrine, and insisted on the position that, although the hypochondriacal and hysterical diseases have many symptoms in common, yet they have also several peculiar ones, which fully manifest an essential difference in their nature. Among the reasons which he assigns for this opinion, some of which are quaintly expressed, is the circumstance that “no hypochondriacs were ever judged to be dead, and intended to be interred, which,” he says, “is credibly reported of hysteric subjects.”

2. *Description of the phenomena.*—A most striking circumstance in the description of hypochondriacal affections is the remarkable difference which is observable between the appearance of the patient and the state of his health as collected from his own account of his symptoms and internal feelings. The indi-

* Sagar. Nosolog.

† Opera Hoffmanni, tom. iii.

vidual who labours under this malady seldom presents any external indication of disease; he has often the appearance of sound and even of robust health: yet, if we listen to his statements, every function of life, every part in the whole fabric of his body, is in a state of disorder, and the source of acute and almost perpetual suffering. It was observed by Hoffmann that as fever is the most general of acute diseases, and pervades the whole frame and every function of the body, so among chronic complaints this seems to be equally extensive in its influence, affecting the nervous system in every part, and every where giving rise to local pains or feelings of distress. The more constant of these complaints are referred to the alimentary canal, and it is in the functions belonging to that part of the animal economy that evident traces of real disease are chiefly to be discovered. The patient complains of distention of the stomach and hypochondria, which are inflated with wind; he often refers his uneasiness chiefly to the left hypochondrium, where there is in reality considerable fulness and induration: in some instances there is considerable enlargement of the abdomen, with a degree of hardness and a feeling of consolidation which excite suspicion of some organic disease. The tongue is generally clean, or covered with a slight brown coat; the stomach is the seat of every symptom of disordered action; the appetite is often irregular, sometimes voracious and hardly to be satisfied; more frequently there is a total want of inclination to eat, and even a loathing of food; after eating, the patient complains of a sense of weight and uneasiness in the stomach; sometimes this amounts to rather severe pain, which recurs at a short interval after every meal; and eructations, cardialgia, or a sense of burning heat at the extremity of the œsophagus, ensue, and after a longer time wind is expelled in large quantity, with a sense of cramp succeeding the effort; sometimes viscid mucus is brought up, with half-digested food and a fluid so strongly acid as to corrugate the throat and set the teeth on edge. In other cases nausea prevails almost constantly, and prevents the patient from taking sufficient food for supporting strength; when a small portion is swallowed it produces great irritation in the system, headach, pulsation in the epigastrium, and flushing in the face; occasionally these symptoms are relieved by vomiting. The patient experiences severe pains through different parts of the abdomen, which he describes as burning, twisting, tearing, and distending the bowels; seizing suddenly different parts of the alimentary canal. He feels a momentary relief when wind is expelled, but the sense of distention soon returns. The bowels are often disposed obstinately to constipation; this state gives way occasionally to looseness; when this last condition supervenes, or when it is brought on by cathartic remedies, all the feelings of distress are aggravated; in addition to his former evils, the patient now suffers an intolerable anxiety, a sense of sinking, fainting, trembling, and apprehends that every minute may be his last: he complains of violent palpitations, pul-

sations of arteries in the abdomen, burning heats, intolerable anguish, whenever his bowels are brought into action.

In the early periods of the disease the complaints refer more particularly to the abdomen; in a more advanced stage this class of symptoms is not diminished, but others are superadded, consisting of a variety of morbid feelings in different parts of the body, but more particularly in the head. Patients complain of violent pains in the forehead and temples, sometimes in the occiput; of severe and distressing headach with intolerance of light. In more frequent cases they experience, not pain, but some indescribable sensations which are more difficult to endure than the most severe pain; a sense of intolerable pressure on the top of the head threatens at every moment to extinguish consciousness and life itself; the head is as if squeezed in a vice, the scalp is drawn tight, and the eyes are felt as if starting out of the sockets; these sensations alternate with vertigo or a feeling of giddiness; the eyes sparkle, twinkle, grow dim; vision is impaired; it is impossible to look at a book or to direct the eyes for a moment to any near object without experiencing a sense of confusion; there is a noise in the ears, like the ringing of bells, bursting, boiling of tea-kettles; rushing of water; the sound of a steam-engine; strange voices; sudden cracklings; whizzings. The power of attention is destroyed, at least the patient is persuaded that such is the fact, though when aroused, by any sudden intrusion, from his tale of sufferings, he is as lively and acute as ever; he cannot think, his ideas are confused. Sometimes he fancies that his understanding is utterly destroyed, that he shall become insane and die in a madhouse. The susceptibility to all impressions on the senses is morbidly increased. Light, sounds, noises, are intolerable. Mental exertion is often the most difficultly endured of all the causes of excitement. If the feelings are aroused, or the attention is kept alive, especially if it be in the later part of the day, sleep is entirely banished, and a state of general irritation is induced.

The mind labours under a degree of morbid excitement in hypochondriac patients; but this is very distinguishable from all the modifications of insanity. The morbid feelings of the hypochondriac are real; they depend on physical disturbances of the system, which he apprehends to be much greater than they are; and this apprehension leads him to dwell upon them, and make them the subject of conversation whenever he has an opportunity of doing so. Yet he sometimes appears to suspect that the long detail of his sufferings may fatigue the patience or excite the contempt of those who listen to him, and he will even suppress a part of the catalogue of his symptoms, which he is at the same time anxious to communicate. The uncomfortable feelings of the hypochondriac are excessively magnified by his fears and the concentration of his thoughts and attention to his disease, and he may sometimes express weariness of life and a desire that his existence may soon terminate; but it is certain that he is

insincere in these expressions, and that he is always under the utmost anxiety to try every possible method for the preservation of his life and the restoration of his health. Such persons will often consult all the physicians of reputation in their vicinity, and will even have recourse to quacks, old wives, and nostrum-mongers; nor is there a remedy that can be suggested too absurd to merit at any rate a trial. An elderly gentleman, who had been for some years labouring under hypochondriasis, combined with amaurosis, sent for a physician in great haste, eagerly requesting an immediate visit. The object of the invalid was to inquire whether any danger would arise from his adopting a remedy which had been strongly recommended by a neighbour or friend. This was to put a piece of stone-brimstone on his head, and walk about the room, having it there fixed. He had been persuaded that some great benefits would be derived from this attempt, if it could only be put in practice without risk. The same individual would describe with the greatest minuteness the sensations which he experienced after taking a dinner-pill, and trace its progress through the whole intestinal canal. He could tell by his feelings where the aloës became dissolved, and where it mixed with the aliment, as exactly as if he had seen through the parietes of the abdomen and the coats of the intestines. He would walk about his room in despair, wringing his hands and bemoaning his condition; yet if any person mentioned by chance the subject of a controversy which he was carrying on in a periodical journal, he would forget all his miseries, and enter into conversation with lively interest.

Besides the morbid sensations referred to the abdomen and the head, there are others which affect the limbs. These are sometimes described as if they were neuralgic pains running along the course of the nerves. More frequently feelings of numbness, deadness, tingling, are described as occurring in the legs, arms, or fingers; the head is said to feel dead and benumbed; sometimes this sensation is referred to the back or to the limbs. Sensations which are considered as more characteristic of hysteria are occasionally described by hypochondriac patients. There is a sort of constriction round the throat, threatening suffocation; but this does not amount to globus hystericus, nor is it accompanied with fits of panting or anhelation. The urine, as in many other disorders affecting the nervous system, is copious and colourless. Sydenham mentions the case of a nobleman who laboured, as he says, under "an hypochondriac cholic." Whenever he was worse, he voided a clear colourless urine, and on any abatement it became straw-coloured. He was nearly convalescent, when some person coming in suddenly and putting him into a violent passion, "he immediately thereupon made a large quantity of very clear water." The limpid urine of hypochondriac patients has been examined by M. Vauquelin, and found to contain rosacic acid.*

The functions of the thoracic viscera are sometimes disturbed in hypochondriasis. As in other diseases attended with dyspepsia and flatulence, the heart suffers interruptions in its action; the pulse is often intermitting, more frequently it is variable and irregular; the patient is troubled occasionally with attacks of palpitation, and these are sometimes so severe, and the action of the heart is so violent, as to excite suspicion of organic disease. Nothing is more certain or better known to medical practitioners than the fact that hypochondriacal and hysterical subjects have often been treated under the impression that they laboured under hypertrophy of the ventricles. In some instances hypochondriasis is attended with attacks of dyspnoea and constriction of the chest, a feeling of something squeezing the throat, and other phenomena approaching to those which characterize the paroxysms of hysteria.

All medical authors who have treated on hypochondriasis, and all judicious physicians who have well considered the complaint, are agreed in testifying that the evils which it inflicts are far from unreal and imaginary. To treat them as such, or to let the patient perceive that we do not fully sympathize with him, that we consider his complaint as one which it is in his power by an effort to shake off, is most impolitic and injudicious. Dr. Cheyne, who gave to this disease the designation of the *English malady*, says emphatically, that "of all the miseries which afflict human life and relate principally to the body, nervous disorders in their extreme and last degrees are the most deplorable and beyond all comparison the worst."

No definite observations can be made as to the rise, progress, and duration of hypochondriasis. The causes are chiefly of slow and continued influence, and their effect displays itself for the most part gradually and almost imperceptibly. The disease has been brought on suddenly by some powerful impression on the nervous system, as, for example, by some cause which occasioned overwhelming grief or vexation, but such instances are comparatively few. It continues for years, sometimes through the life of the individual, who cannot escape from the exciting causes which gave rise to it; but it does not of itself shorten life. There is reason, however, to believe that hypochondriacs are more subject than other persons to acquire organic diseases of the abdominal as well as the thoracic viscera; yet on this subject no exact reports are to be found. The long duration of the disease, the circumstance that persons who labour under it are seldom throughout its course under the care of the same practitioners, and especially that they do not in the ordinary course of things die in hospitals, are sufficient to account for the deficiency of exact information on these points.

3. *Diagnosis.*—One of the most difficult considerations connected with hypochondriasis is the diagnosis of this disease from others with which it is more or less liable to be confounded, and this is likewise the most important point of view in which the subject

* M. Georget, Dict. de Médecine.

can be contemplated. The complaints of the hypochondriac are so multimform that they suggest a great variety of morbid affections, and some of these are among the most severe diseases to which the animal economy is subject. The disorders which are symptomatic of hypochondriasis must in their turn be distinguished from the organic diseases which they simulate, or some fatal error will be likely to arise when the medical practitioner either pursues a more active method of practice than the real circumstances of the case require, or neglects to adopt energetic remedies when absolutely necessary in order to avert impending danger.

When an individual is known to labour under hypochondriasis, this circumstance will often throw light on the nature of his temporary ailments. If such a person complains of dreadful pains in the head, vertigo, temporary loss of sensation and of memory, or of palpitation or intermission of pulse, we shall be on our guard, and shall less readily ascribe such complaints to disease in the head or in the heart, than if they occurred in patients under different circumstances. Still the diagnosis is imperfect unless it is absolute on the negative side, for hypochondriacs may and do become the subjects of organic diseases. Nor is the constitutional disorder of these persons always so marked as we might imagine from the foregoing description of their disease. Hypochondriasis does not affect simultaneously and in every case all the functions said to become deranged. Sometimes its manifestations are distinct and strongly marked in the state of the abdominal viscera, and in such cases there is comparatively little ground for mistake. Sometimes the functions of the heart are considerably deranged when the symptoms are elsewhere obscure. In these instances we know that experienced and skilful practitioners have been deceived. When the disorder is principally seated in the head, it likewise occasions difficulties; and these difficulties are not lessened by the circumstance that the diagnosis is on the negative side.

In order to distinguish hypochondriasis from diseases locally affecting the abdomen, an attentive examination will sometimes be required. (See ABDOMEN, EXPLORATION OF THE.) Care must be taken to distinguish the disorder which we are now considering from organic diseases of the stomach, in cases attended with long continued vomiting of the ingesta; from affections of the liver and pancreas; from the results of stricture in the intestinal canal: in other instances, from recent though still subacute diseases of the same canal, as from gastro-enteritis, which Broussais is disposed to identify with hypochondriasis. The latter distinction is not always exempt from difficulty; there are many obscure cases in which the disorders are intermixed; and where they exist separately, the diagnosis is not so easy as many persons may be inclined to imagine. We cannot wholly rely on the presence or absence of pain when pressure is made on the abdomen. Little or no pain is in general produced by such pressure in cases of

hypochondriasis; and it commonly occasions suffering in some part, when there is much abdominal inflammation. But the mucous membrane of the bowels may be the seat of disease without giving occasion to pain on pressure. On the other hand, hypochondriacs are ready to exclaim whenever they are touched; the excited state of their apprehension augments the real feeling of uneasiness, which depends upon increased sensibility of the subcutaneous nerves. It will be found, however, that they bear a strong and continued impression better than a slight and momentary one. The state of the bowels in hypochondriasis is generally rather constipated, and often loose and irritable in gastro-enteritis; but these observations are not very unfrequently reversed. The absence of febrile symptoms; the capability of using exercise; the more healthy appearance of the countenance; the preservation of muscular strength and fulness, with the condition of the appetite, which in many cases of hypochondriasis is unimpaired, and in others greater than usual; will in most instances enable the practitioner to distinguish this disease from gastro-enteric inflammation.

The signs have often been laid down by which disorders of the heart depending upon organic causes are distinguishable from the irregularities arising from dyspeptic and nervous complaints. During the paroxysms of palpitation which belong to this latter description of diseases, symptoms are often perceived which lead to the suspicion of organic affection. M. Andral has indeed observed that the pulsations of the heart are often irregular, and accompanied with a "*bruit de soufflet*" in cases purely hypochondriacal or nervous. He has observed violent palpitation succeed during the interval of the attacks by morbid dyspnoea and even perceptible swelling of the face, in cases which were independent of any organic disease of the heart.

These remarks will be sufficient to shew that practitioners should be upon their guard in pronouncing as to the nature of disorders in the functions of the heart affecting hypochondriacs. It would be superfluous under this head to go into detail on the pathognomonic signs of organic diseases of the heart, as these have been fully considered in their proper place. The proof that complaints referred to the heart are hypochondriacal and not organic is likewise in a great measure of a negative kind. If the patient is low-spirited and nervous, if he has been known to be subject to hypochondriasis, the probability is on this side. If he has never undergone any apoplectic, epileptic, or paralytic attack; if he preserves his natural and habitual degree of muscular power, and his senses are not in any way impaired; if all the functions of his brain are uninjured, we may almost venture to conclude that the complaints which he makes of morbid sensations in the head do not indicate so much danger as he supposes. Still, when these complaints are accompanied by discoverable signs of irregular circulation; when the vessels are full and beating forcibly, the head hot and

flushed; and when the general appearance indicates a plethoric state of the vascular system in the head, it will be advisable to relieve this state by depletion, either general or local, according to circumstances.

Hypochondriasis must be distinguished from insanity. The discrimination is not difficult. Persons who labour under the former disease have possession of their reason, and the sufferings they describe are really experienced by them, though not so dangerous as they are supposed by the sufferer to be. If a hypochondriac begins to declare that his head or his nose is too large to pass through a doorway, or displays any other hallucination, he has become a lunatic: his disorder has changed its nature, and this conversion takes place occasionally, though it is by no means so frequent as many persons probably apprehend. Hypochondriacs, though low-spirited and dejected, are in a very different state of existence from persons labouring under melancholia. The apprehensions of the former are all centred on the state of their bodily health: on other subjects, they think and often converse rationally and with cheerfulness. The melancholic views all things through a medium of gloom and despondency. Lastly, the feelings and affections of hypochondriacs are not in that perverted and unnatural state which is one of the characteristics of madness in nearly all its forms.

Causes of hypochondriasis.—There is no particular constitution or temperament of body, at least there is none distinguished by known external characters, that is remarkably subject more than others to hypochondriasis. We have observed this disease frequently affecting persons who bore all the external marks of the sanguine temperament as well as others who had the characters of the melancholic.

The middle period of life, and perhaps the interval between the twenty-fifth and the fiftieth year is the age which is principally disposed to this disease. It seldom attacks young persons, or, for the first time, those advanced in years. Men are more subject to it than women, though in the latter it not unfrequently occurs. This, however, is seldom the case in respect to young females. With them disorders of the nervous system are more disposed to assume the character of hysteria. Females upwards of fifty years of age are often subject to dyspepsia, flatulence, eructations, gastrodynia, attended with gloom, depression of spirits, and other symptoms of the hypochondriac malady, though not frequently in so strongly marked a form as that which it assumes in men.

The predisposing causes of hypochondriasis, or the antecedent circumstances which are followed by that disease, belong to two different classes, one of which are influences affecting the mind directly and the functions of the body only through this medium: the other series of morbid agents produce their effect, in the first instance, on the abdominal viscera and the processes of physical life; the affection of the mind which follows being apparently dependent on this derangement.

These morbid influences are sometimes blended in the habits of life which produce a peculiar tendency to hypochondriasis. Such are the modes of existence which allow of little bodily exercise, and at the same time occasion an overstrained and continued exertion of the mind. The state of manners in civilized society gives rise to this unfortunate combination of circumstances in a thousand ways, and multiplies, together with the comforts of life, all the sources of mental fatigue and over-exertion, and consequently the number of hypochondriacs. Intense and long-continued exercise of the intellect in one pursuit, whatever it may be, is frequently the cause of this disease. Hence hypochondriasis has been termed the disorder of literary men, "*morbus literatorum*;" and Hoffmann says that its victims are chiefly "*virī chartis impallescences et inter libros sepulti*." Clergymen, schoolmasters, persons employed in diplomatic business, and in other occupations requiring activity of mind, and giving occasion to sedentary habits, are equally liable to be attacked by it.

Among the classes of sedentary men who frequently become hypochondriacal are tailors and shoemakers. Their constant habit of sitting at their trades, and their peculiar modes of sitting, probably occasion a torpid state of the intestinal canal, and disorder of the functions connected with it. Their minds are also active beyond their craft; witness the proverb, *ne sutor*, &c. and the number of preachers, theologians, founders of sects, and political reformers, who have arisen from the cobbler's stall and the tailor's board.

There are other classes of persons whose predisposition to hypochondriasis cannot be explained in the same way. Agricultural labourers, men who spend a great portion of their time in working in fields, in digging, making and mending hedges and ditches, and in solitary employments in the country, are frequently affected with low spirits and the other characteristics of this disorder. The solitariness of their employments is probably the chief predisposing circumstance.

Some medical authors are inclined to suppose that hypochondriasis arises almost solely from causes affecting immediately the brain and nervous system. Several French writers have maintained this opinion, and probably it may be better supported by facts in France than in this country. M. Louyer de Villermay, in his work entitled "*Traité des Maladies Nerveuses*," has adduced evidence which bears upon this inquiry, and it is only to be regretted that the sphere from which it was drawn was not more extensive. Out of thirty-six cases of hypochondriasis recorded by this writer, the disease appears to have arisen in twenty-two from "*moral affections of a painful description*," by which we are to understand causes giving rise to mental distress: in eight cases out of the same number it was occasioned by too close application to study; in two it arose from fright or sudden alarm; in two it followed an immediate transition from a state of life requiring great activity to one of ease

and leisure. These facts are favourable to the opinion that hypochondriasis is a primary disorder of the nervous system, a conclusion which has been adopted and supported with much ingenuity by M. Georget. This writer considers the disease in question to be one of the brain, excited by the influence of moral agents, or by those causes which act in a hurtful manner on the mind, and through that medium on the brain. He observes, in support of this opinion, that hypochondriasis is most common in the higher classes of society, among persons occupied in official and diplomatic business, or devoted to literary pursuits. "England," he adds, "is perhaps the country where this species of nervous disease chiefly abounds: this is principally owing to the prodigious activity of mind which exists in that country; to the miseries which are contingent on the great development of industry; to fortunes rapidly acquired in commerce by a number of individuals who subsequently pass their whole lives without employment, in excesses of every description." In this last particular, M. Georget has expressed himself rather conjecturally than from a knowledge of facts. It cannot be truly said that a considerable proportion of those persons who accumulate property in this country by the exertions of industry, abandon themselves afterwards to excesses of all descriptions. Indeed the excesses of vulgar dissipation are not to be reckoned among the ordinary causes of hypochondriasis. This disease seldom attacks persons who are addicted to the immoderate use of fermented liquors; it rather falls to the lot of those who are abstemious in this respect.

Hypochondriasis is not in reality confined to the better classes of society, or to persons of cultivated minds, on whom moral causes may be supposed to act with the most extensive influence. Cases occur frequently in hospitals, and therefore among the lower orders. The writer of the present article has had under his care, or at least under his occasional observation upwards of twenty years, two patients of this description who are among the most ignorant of the lower class of peasants. They both furnish strongly-marked examples of hypochondriasis; both have been tormented during a great part of the space above mentioned by the numerous and frequently varying but ideal miseries which accompany that disease. In both of these persons the nervous system appears to have been originally weak and susceptible of impressions; but the causes which actually gave rise to morbid phenomena in their constitutions could scarcely belong to the class of moral agents; they were circumstances which induced disorder in the physical or natural functions. The same conclusion may be drawn with great probability in most of those instances of hypochondriasis which occur among persons of the lower classes.

We may state in a summary manner that the causes which occasion hypochondriasis as an idiopathic complaint are, agents which exercise an hurtful influence on the mind, and through it on the nervous system; too intense and long continued application; studies

and professions which require great intellectual exertion; anxiety respecting the success of schemes and prospects of worldly advancement; disappointment of various kinds, and consequent dejection; and lastly, though this is by no means the least important article in the catalogue, the indulgence of vicious habits which tend to debilitate the mind and body. The noxious influence of these causes is exerted in the first place on the nervous system; the functions of physical life are affected by sympathy; nor are such affections difficult to understand or to reduce to the general analogy of facts in pathology; but this is a consideration which belongs to the next section.

There are very many instances of hypochondriasis in which, as we have before suggested, the predisposing causes are those which give rise in the first place to dyspeptic ailments, and to disordered actions of various kinds in the alimentary canal. Sedentary habits, a poor diet, the abundant use of warm diluent fluids, tea, coffee, and the like, a constipated state of the bowels subsisting habitually and long continued, are the most frequent of the causes reducible to this class. The disease appears to be more common among the lower ranks of society in this country than in France, and that, if we are not mistaken, is particularly the case with respect to women. A great number of the wives of cottagers, and old women who live with their own families, and not in domestic service, are fed in England chiefly on bread and tea, seldom getting either much animal food or any fermented liquors. Of these a considerable proportion are dyspeptic and many are hypochondriacal.

Pathology.—Anatomical researches have thrown no light on the pathology of hypochondriasis, nor does it appear probable that the subject will ever be elucidated by such means. Organic changes of almost every description have been discovered in the bodies of persons who have been the subjects of this malady. Their diversity is too great to allow of the supposition that they are all connected with one complaint. The individuals in whose bodies they have been discovered have terminated their existence under various diseases. Hence the diversity of morbid phenomena, which, if it were possible to trace the connection of causes and effects, would probably be found to have stood in no near relation to the hypochondriacal ailments which affected the individuals in question without endangering life, or ultimately accelerating its termination.

Medical writers have long been divided in their opinions with respect to the seat and nature of hypochondriasis. Some have regarded it as a primary disease of the nervous system in general, or of the brain itself; while others have looked upon the affections of the nervous system as secondary, and depending upon sympathy with a disordered state of functions belonging to the abdominal viscera. These opposite opinions were espoused by Sydenham and Hoffmann, and each of them has found advocates among distinguished writers of the present time.

Sydenham, as we have before observed, considered hypochondriasis and hysteria as closely analogous, or rather as modifications of the same disease, depending merely upon sex. He says, that "the disturbed or variable disposition both of mind and body which prevails in hysteric and hypochondriac subjects arises from a disorder of the animal spirits, or from an inordinate motion of the spirits."—"The spirits," he says, "which are subservient to the mind are, in reality, composed of the finest particles of matter, and border upon immaterial or spiritual beings." Sydenham's expression, "a disorder of the animal spirits," translated into the medical phraseology which is current in our own times, is well known to mean a disordered state in the functions of the nervous system. In connexion with this opinion as to the nature of the disorder, the author remarks that it occurs to those whose minds, or rather whose nervous systems were "originally weak or have been rendered so by a long train of disorders, or their long continuance."

Hoffmann maintained the opinion that hypochondriacal maladies proceed originally from disorders of the stomach and intestinal canal, from irregularities in its peristaltic action, whence ensue dyspepsia, flatulence, colic pains, spasms, and all the local symptoms which gave to the disease the name of hypochondriasis. The general disorders of the nervous system are supposed by this writer to depend on sympathy.

The opinion which ascribes to hypochondriasis a local origin has been reduced to a more definite form by modern writers. M. Louyer Villermay, in his treatise on nervous diseases, maintains that the primary seat of the complaint is in the abdominal viscera, and especially in the stomach. Here, according to Villermay and many who have adopted his opinion, the disease consists in a morbid state of the nervous structure and of the vital properties of the parts, and chiefly in an excess of their organic sensibility, an expression which belongs to the school of Bichat. The disorders which affect other organs and nearly the whole animal economy in hypochondriasis, are the results of sympathy with the morbid condition of the nervous structure connected with the gastric system.

M. Broussais and his followers modify this theory according to their peculiar and favourite doctrines. The disease, according to M. Broussais, is seated primarily in the coats of the stomach, but it is not a merely nervous affection. It is the same state, or analogous to the same morbid state, from which so many other manifestations of disease in various parts of the system arise; namely, a chronic inflammation of the mucous membrane of the stomach. From the peculiar condition of this membrane with respect to its vascularity, arises its morbid sensibility, and from sympathy of other parts of the system ensue all the multiform phenomena of hypochondriasis.

M. Georget has strongly opposed the opinion of those who place the primitive seat

of hypochondriasis in the abdominal viscera. In his work entitled "*Physiologie et Maladies du Système Nerveux*," he has investigated this subject, and has deduced from his own observations, and from facts reported by various authors, the following inferences:—

1st, That the characteristic phenomena of this disease refer themselves to the head. 2dly, That the other symptoms which sometimes belong to cases of hypochondriasis are not constant: thus we find that there are some cases in which palpitation of the heart has been remarked; there are others in which no remarkable derangement in the digestive processes has been observed. 3rdly, That almost all the exciting causes of the disease are such as are known to exert their influence directly on the cerebral functions. 4thly, That the most efficacious methods of treatment are moral remedies. From these considerations the author has drawn the conclusion that hypochondriasis is a primary affection of the brain.

It is impossible to give due attention to the arguments adduced by M. Georget on this subject without being aware that they have considerable weight. And yet the inference seems rather strongly drawn when we advert to the fact admitted on all hands, that no disease whatever has been traced with certainty in the brains of hypochondriacs. It must be taken into the account that morbid causes may, and do occasionally, act through the intervention of the brain, and induce disorders in other parts of the system much more real and considerable than the derangement occasioned, *in transitu*, in the brain. A man may receive some afflicting intelligence just before he is going to dinner, which may so spoil his appetite that he cannot eat. The function of the stomach is here impeded and deranged; not so that of the brain, although the impression is undoubtedly communicated through the instrumentality of the brain. In like manner trains of morbid causes may bring on repeated and at length habitual derangement in the functions of the alimentary canal, and of all the parts connected with it in structure and operation. These causes act through the instrumentality of the brain, but they are not productive of actual disease in the structure at least of that organ.

These considerations throw light on some of the theoretical questions connected with hypochondriasis. They tend to explain, so far as the analogy of facts occurring in the animal economy affords explanation, the circumstance that disorders in the natural functions, and particularly in those of digestion, arise from causes acting on the nervous system, and this without necessarily involving the supposition that there is disease actually seated in the brain and nervous system. The consideration that hypochondriasis is a disorder frequently, perhaps chiefly in its most aggravated forms, arising from the influence of causes which act, in the first place, upon the mind and on the brain, is therefore no adequate proof that the brain is disordered. The condition of the sensitive

and intellectual powers, which are uninjured in this disease, seems to afford a presumption on the negative side of this question. Still, when we take into the account the mental dejection of hypochondriacs, the habitual state of their spirits, and the trains of morbid feelings, of painful sensations which torment them, we can scarcely refuse to admit that some unknown deviation from the healthy and natural state of the cerebral functions lies at the foundation of their ailments, though it is remote from organic disease, and of a kind of which we can form no conception. Many of the phenomena which accompany this disorder would lead to the opinion that the principal deviation from health and the natural state of functions is situated in some other part of the nervous fabric rather than in the brain. They might be thought referable to the system of ganglions in connexion with the great sympathetic, or to what has been termed the nervous system of the viscera or of physical or organic life; since in this is the immediate centre, as it appears probable, of that peculiar property or influence termed organic sensibility in the stomach and other abdominal viscera. But phenomena involving consciousness and affections of the mind can hardly be confined to this part of the nervous system; the brain must participate in the morbid disposition; unless we could persuade ourselves to believe, with Bichat, that the feelings or pathemata have their proper seat in the ganglionic apparatus.

We shall close this part of our subject by adverting to a circumstance which confirms the conclusion that hypochondriasis is a disease of the nervous system rather than of the digestive organs themselves. It is the fact that the complaint is in some instances suspended through long intervals of time, during which the individual subject to it is in perfect health. We have known hypochondriasis to attack the same person several times during his life. A gentleman, previously healthy, active, and vigorous in mind and body, temperate, and regular in all his habits, became, without any assignable cause, low-spirited, anxious about his health, fancying that he was in imminent danger of various diseases of which he could trace slight and evanescent symptoms in his own feelings. He then began to complain of indescribable sensations about the stomach, burning pains in the epigastrium, flatulence, sinking, internal weakness; of pressure on the brain, and various symptoms of distress referable to the head; in short, of nearly the whole train of symptoms which characterize the most complete examples of hypochondriasis. These complaints molested the unfortunate sufferer for several months: no remedies appeared to be of any service. At length the symptoms disappeared and he regained perfect health, which he enjoyed for an interval of several years. During this period he bore no trace of any disease in the digestive organs. On the contrary, all the functions of physical life went on in a perfectly regular way. The attacks of his disease have recurred several times, and with the depression of spirits all the dyspeptic

symptoms returned. It might, indeed, here be a question, whether the return of gastric and enteric disorder brought with it the recurrence of nervous symptoms, or conversely, whether the relapse into disease of the nervous system was the occasion of renewed dyspepsia. The latter supposition is by far the most probable. Habitual disorders of the digestive functions are not frequently observed thus to cease altogether, and to recur without any distinct and perceptible causes. They do not leave their victims for some years in a state of perfect immunity from their influence, and attack him again in renewed and distant periods, while this is conspicuously the case with complaints affecting the brain and nerves: cases like that which we have described seem to approximate hypochondriasis to the class of disorders affecting primarily the nervous structure. They are incompatible with the supposition that chronic disturbance of the alimentary canal constitutes the whole essence of the disease.

But although it seems to be sufficiently evident that the actual seat of hypochondriasis, or the part of the organised fabric on the disordered state of which its characteristic symptoms depend, is the brain and nervous system, yet it cannot be doubted, on a consideration of the predisposing causes, that the latter in some cases exert their primary influence on the state of the abdominal viscera. Severe and long-continued disorder of the digestive organs lays the foundation for hypochondriasis; as similar influences occasion other diseases of the nervous system. As long as the mind is unaffected, the complaint may be considered as simple dyspepsia, and the whole of the disease may be regarded as confined to the digestive organs; but when low spirits and dejection are manifested, and hypochondriasis properly so termed exists, the disease must be supposed to have involved the nervous system, and in some degree the brain.

Treatment.—The treatment of hypochondriasis would be easy and probably in most instances successful, if it was taken up on rational principles from the commencement of the disease or early in its course. This seldom happens to be the case. It is rarely that hypochondriacal patients apply for the advice of a physician until the failure of a variety of remedies administered by themselves drives them to seek for aid likely to be more availing. When such an application is made, it is generally found that the patient has been a great reader of medical books; that he has repeatedly experienced in his own person the effects of every specific drug reputed to restore the functions of the liver and the chylipoietic system. It will often be found impossible to prescribe any remedy which has not already been tried, and given up in despair. Under such circumstances, the wisest course a physician could pursue, would be to repeat the precept of Montanus, often cited with applause, "*Fuge medicos et medicamenta, facillique convalesces.*"

The treatment of hypochondriasis should be divided into two departments, the dietetical or

moral, and the pharmaceutical. Of these the former is by far the more important, whether in recent or inveterate cases.

The first indication which common sense points out for the relief or cure of hypochondriasis, and the beneficial tendency of which is confirmed by experience, is to remove the causes of the disease by laying aside the habits, and as far as possible reversing the moral influences which have occasioned it. Change of scene, a removal from customary occupations by travelling, is the best method of ensuring this object. In the good old times, when physicians had a double hold on the obedience of their patients, the monkish practitioners had an excellent resource in prescribing for hypochondriacs a pilgrimage to the tomb of St. Jago, or the shrine of the Three Kings; but when their patients had lost all faith in the relics of Melchior, it became necessary to substitute other expedients which are not always quite so innocent. The most popular of these has been a resort to mineral springs; Hoffmann extols the waters of Schwalbach and Pymont. Various medicinal springs have afforded a pretext for advising sick persons to remove from home, and out of the influence of circumstances which created and fostered their disease. The physician who has hypochondriac persons under his care will avail himself of those means for fulfilling the indication above suggested, which may best accord with the circumstances and the prejudices of his patients. Continued travelling has the best effect, and is on many accounts preferable to an abode in any one place. Even the accidents of diet and lodging to which travellers are exposed are often productive of benefit to patients of this class: and when such circumstances produce temporary disorders of a different kind, as rheumatism, colds, slight bowel complaints, minor evils of this description are found to take off the attention of the patient from his habitual malady, and even tend to introduce, when they begin to abate, a better state of health and spirits. A gentleman who had been for many months labouring under great nervous susceptibility, dyspeptic, and unable to take food without producing great excitement and distress, set out in this state to make a journey in the south of Europe. He was seized on his way with diarrhoea, which was kept up by the acid cookery and wines of France, and continued for some weeks. Instead of increasing his principal malady, these accidents materially lessened it, and even before the new disorder entirely ceased, all the old series of complaints, both of the digestive functions and the spirits, were in a great measure cured.

As the effect of remedies in these instances depends not less on their influence on the mind than on the body, patients should be advised to go to places where their attention is likely to be occupied; this must be determined by circumstances.

Habitual and regular exercise is very conducive to recovery from hypochondriasis. Sydenham says, "the best thing I have hitherto

found for strengthening and cheering the spirits is riding on horseback some hours every day." He gives an instance of the efficiency of this remedy, in a "learned and reverend prelate, who, having applied himself too intensely to his studies for a long time, was at length attacked by a hypochondriac disorder which destroyed his digestion." After trying various remedies in vain, when reduced to great weakness by a colliquative looseness, he at length consulted Sydenham, who "immediately judged that it would be useless to order any more medicines as he had taken so many already, and, therefore, advised riding on horseback, directing him to take only such short journeys at first as he could bear without fatigue." "I entreated him," says Sydenham, "to continue it every day, to lengthen his journeys by degrees, and not to mind either meat, or drink, or the weather, and to take up with such accommodations as he met with on the road like a traveller. In short, he continued this method, till at length he rode twenty or thirty miles a day, and finding himself mended in a few days, he was encouraged by this wonderful success to continue in the same course for several months, in which space of time he rode several thousand miles. He was at length not only freed from his disorder, but became strong and brisk."

When the patient cannot ride on horseback, some other mode of exercise must be substituted. Walking is the most advisable, if the strength admits of it. Even females, when labouring under hypochondriasis, have derived great benefit from the practice of walking several miles every day, and by constantly observing the rule to do so when not prevented by intemperate weather.

The most effectual, however, of all rules for the cure of hypochondriacal patients is to withdraw them from studies, or pursuits, or habits of whatever kind, which may have been connected with the formation and development of their disease. If this maxim cannot be fully acted upon, which will unfortunately happen in a great number of instances, it must ever be borne in mind, and followed to the utmost limit which the circumstances of the invalid will admit. In all cases it must be remembered that much depends upon keeping the mind as much as possible agreeably and actively engaged. Irreparable evils may ensue from allowing the patient to sink into a state of mental vacancy and despondency, and to brood on his own uncomfortable feelings.

Something may be contributed towards the cure of hypochondriasis in many instances, and perhaps in all towards its mitigation and the relief of symptoms, by medicinal remedies. The choice and mode of administering these must depend upon the state of gastric and intestinal disorder with which the other ailments of the system are complicated. It will be well to bear in mind Broussais's theory of the disease, which is not without foundation in truth. If gastro-enteritis, or an inflamed or highly irritable state of the mucous membrane exists, of which there are frequently indications

more or less strongly marked, the case must be treated accordingly. All stimulating remedies will then be improper, and the regimen most likely to prove beneficial will be the antiphlogistic. An attenuating diet, with semi-fluid farinaceous nutriment and cool drinks, the use of mild injections and the most gentle laxatives for the purpose of regulating the bowels, the occasional application of leeches to the abdomen, warm bathing, will be the principal means of relief. When the dyspeptic maladies are without any inflammatory combination, and allied to atony or want of strength and action in the alimentary canal, warm purgatives, combined with bitters, aromatics, and the drugs termed antispasmodic or nervine, are most serviceable. Rhubarb, or infusion of senna and gentian, with some aromatic tincture, may be given daily or occasionally; with them alkaline or neutral salts may be combined according to circumstances. Aloetics, and compounds containing other resinous purgatives, may be added if necessary, and combined with assafetida or the galbanum pill. The remedy which agrees with the greatest number of flatulent and dyspeptic persons for the longest period is composed of a drachm of powdered rhubarb in half a pint of warm peppermint water.

Tonic remedies are used with advantage in some cases of hypochondriasis; and of the class of drugs so termed, the sulphate of quinia and the sulphate or subcarbonate of iron are the most efficacious. The subnitrate of bismuth may almost be considered as the sole remedy of the kind in cases attended with gastralgia after eating, and with pyrosis. It may, perhaps, be superfluous to observe that all the remedies of this class are highly injurious in cases attended with a state of the intestinal canal bordering on gastro-enteritis.

(J. C. Prichard.)

HYSTERIA.—Hysteria is a name commonly given to certain paroxysms of disorder occurring in peculiar constitutions, and generally in females; but in its full signification comprehends several peculiarities of a permanent character, as well as peculiar phenomena of occasional occurrence not amounting to the hysteric paroxysm. The latter phenomena sometimes appear singly, and sometimes in connexion with morbid actions not hysterical, but to which they impart a peculiar or hysteric modification. Thus defined, and the definition will be found of practical application, we may almost admit without qualification the remark of Sydenham, that hysterical disorders constitute one-half of all chronic distempers.

The circumstances of the hysteric paroxysm may in part be described from observation; but some of them are only perceived by the individual affected. Of the latter kind is the sensation of a ball or solid body suddenly perceived in some part of the abdomen, and usually in the left iliac region, or in a situation corresponding to that of the sigmoid flexure of the colon. It is probable that accurate observation would detect a circumscribed swelling or ful-

ness in that situation when the sensation comes on; but, both on account of the short duration of the symptom, and for other reasons easy to be imagined, this fact is generally taken on the testimony of the patient. A kind of vermicular motion of the abdominal muscles, and the sudden elevation and depression of the abdominal surface have been observed. There are, also, some precursory symptoms which are very troublesome to the patient, but not very easily described, concurring to produce what is called a *general* uneasiness and oppression; together with the more distinct symptoms of stiffness about the larynx, headach, and cramps. M. Georget says that the hysteric patients in the hospital of the Salpêtrière are so well accustomed to take warning by these precursory symptoms as never to be seized unexpectedly: they go to bed and are tied down until the fit is over.

The sensation of the ball, or globus, is described as ascending to the stomach, and then up the chest to the neck, becoming fixed in the throat; and to this sensation physicians have given the name of *globus hystericus*. In some persons who are liable to it on particular occasions, and in others who are occasionally affected with violent hysteria, the paroxysm of hysteria may end here. But in many, whilst the sensation itself is very distressing, it is attended with a sense of coldness and stiffness in the legs or in the trunk of the body, a depression of spirits, noise in the ears, and vertigo; and to these symptoms succeeds a temporary loss of sense and consciousness, and of command over the muscles of voluntary motion, which are either motionless, or violently and involuntarily agitated; the arms and legs being most generally affected, in short but repeated paroxysms, with vehement struggles, during which one of the hands is frequently struck on the breast, or the head lifted up and struck violently against the bed or the floor, or the patients tear their hair or otherwise injure themselves. Whilst these attacks last, the action of the heart is generally vehement, subsiding at intervals, but becoming again excited when a new paroxysm is coming on: the carotids are seen to beat strongly, and the veins in the neck swell. The face is flushed, and the skin is hot. The muscles of respiration are in almost every case especially affected; the patient breathes slowly, deeply, and as if by sudden impulses; or sighs profoundly, or sobs heavily, or cries or laughs immoderately and without meaning. Violent expiratory efforts are made, seemingly opposed by spasmodic action of the glottis;* the hands are forcibly applied to the throat, as if the patient felt a painful spasm there, and suffocation was impending: sometimes the epigastrium seems to be the seat of intense suffering, and is rubbed or even violently struck by the patient. Some patients bite their hands or arms, or those of

* Emphysema has sometimes ensued; supposed to proceed from the air being forced through the cellular tissue and mediastinum. See the article **EMPHYSEMA** in this volume, p. 16.

the unguarded bystanders. Occasionally, the bladder is affected with irregular action, and pale urine is copiously ejected.

Of a paroxysm of this kind the duration is uncertain; varying from a quarter of an hour to several hours. The recovery from it is often sudden and complete; a flood of tears, a burst of laughter, or a cry like that of one suddenly awakened, frequently ends it; or the patient, apparently exhausted, sinks into a state of quietude from which the recovery may be either sudden or gradual. The patient is sometimes unconscious of what has been going on around her, but is not unfrequently able to repeat what has been said by the assistants during the fit; a circumstance which not only suggests certain cautions to the practitioner, but has been made use of in the cure of this troublesome malady.

After such an attack, there is in some instances a temporary impairment or loss of voice, or of some of the muscles of voluntary or involuntary motion, as a paralysis of the arm, or of the bladder. In general, the only consequences are a degree of fatigue, and headache.

Such is the common form of the hysteric paroxysm; but it is subject to varieties, the distinction of which is on some occasions extremely important to the medical attendant, as well as to the patient. "This disease," says Sydenham, whose description of it is very minute and accurate, "is not more remarkable for its frequency than for the numerous forms under which it appears, resembling most of the distempers wherewith mankind are afflicted. For in whatever part of the body it be seated, it immediately produces such symptoms as are peculiar thereto; so that unless a physician be a person of judgment and penetration, he will be mistaken, and suppose such symptoms to arise from some essential disease of this or that particular part, and not from the hysteric passion."* Unusual forms of sudden illness, or unexpected circumstances in the course of disorders familiar to the observers, often excite much alarm until their hysterical character and origin are recognized. Every form of hysteria, however various and transient, is, therefore, sufficiently important to deserve the attentive observation of the student of medicine: nothing else can lead to their ready recognition in future practice, where a mistake may prolong needless anxieties, and be even of serious consequence both to the practitioner and patient; affecting the safety of one and the reputation for discernment of the other.

The ordinary varieties of the hysteric paroxysm chiefly consist of certain limitations of the preceding phenomena, with more or less aggravation of their severity in the parts or functions which happen in each case to be their seat. In many cases the symptom of globus, commencing in the abdomen, is accompanied with an incredible development of air in the intestines, which produces great distention and oppression, induces dyspnoea,

various pains both in the abdomen and chest, and a sense of constriction in the throat, with irregular breathing or crying; but does not go on to convulsions of the voluntary muscles, nor to insensibility and complete loss of power. These attacks come on, perhaps, a few hours after dinner, and last for two or three hours: an immense quantity of air is at length got rid of by eructation, and then all the symptoms subside. If the eructation does not take place, the patient complains of severe anguish in the situation of the stomach; or, becoming too much oppressed to speak, rubs the epigastrium vehemently with her hand. There is evident distention of the upper part of the abdomen, which may, without eructation, gradually subside; and there is often great commotion in the greater part of the intestinal track, productive of violent rumbling, sometimes with alternate protrusion and subsidence of different portions of the abdominal parietes. But whilst the distention remains, other symptoms may supervene, apparently excited by it; as disturbance of the circulation in the form of palpitation; determination of blood to the head, producing severe pain, sometimes with vertigo, flushing of the face, suffusion of the eyes, and some degree of mental oppression or torpor; all of which seem in certain cases to be secondary to the gastro-intestinal distention or tympany. To these symptoms, or to a part of them, succeed in other patients all the other circumstances of the hysteric fit; the muscular agitation, the loss of the sensorial and muscular power, and the consequences of these accidents.

Certain obstinate cases of indigestion in females are in reality hysterical. The patients complain of much oppression after eating; the oppression sometimes amounts to temporary stupor, with a feeling of inability to move, which yields, however, to strong efforts or excitement: occasionally true hysteric symptoms, globus, disturbed breathing, convulsions, and insensibility, succeed, and even in the lighter forms give relief.

The irritability and disorder of the stomach in hysterical subjects is in some cases manifested by the occurrence of vomiting; the matter vomited being green, or black and like the grounds of coffee. (*Whytt.*) We have never known hematemesis occur in the fit, as mentioned by Georget. The appetite is very irregular, often craving things hurtful, and at hurtful hours, as meat, cheese, cucumber, &c. at night, and then only. Great depression of spirits is generally conjoined with these states of gastric disorder, and proneness to tears.

As no organs of the body sympathise more with the nervous system under the various impressions made upon it than those concerned in the function of respiration, so the hysteric constitution is particularly liable to disturbances of this function. The intense susceptibility of such a constitution leads to the occurrence of hurried breathing when even slight emotions are experienced; and to sighing, sobbing, and violent inspiration and expiration when any of a more powerful kind are excited. There

* Swan's Translation, Lond. 1749. p. 370.

are patients in whom hysteria manifests itself chiefly by these irregularities, which are more or less induced in different individuals; in some very readily, being in them only transient in their existence; in others with more difficulty, and, when produced, evincing more violence and less facility of being controlled. The irregularity of breathing, occurring in paroxysms, and induced by accident, sometimes very closely simulates asthma; and this solution of paroxysms apparently asthmatic may be sought for with success when they occur in young persons rather than in older, and in females of an irritable temperament: the apparent asthma will often be found co-existent with other and less doubtful hysterical phenomena, and will admit of considerable or of permanent relief from what are called anti-hysterical remedies.

A loud, disturbing, dry cough, almost resembling a bark, is so peculiar to hysteria that it might well be called the hysterical cough. It occurs in paroxysms, and is brought on with much violence by slight mental impressions, as by an unexpected visit from a friend, or the approach of the medical practitioner. Individuals thus affected are commonly subject to all the other symptoms of hysteria. In some patients the hysterical attack comes on with an apparent spasm of the glottis, and a croupal respiration; in others it assumes the form of common asthma. Dr. Ferriar speaks of an hysterical hemoptysis, relieved on the super-vention of the fit; but this, and the copious expectoration with profuse night-sweats, described by most of the older authors among the troubles of hysteria, we have not observed.

We were not long since in attendance on a patient of about thirty-five years of age, in whom there was a deficient, although regular, performance of the uterine functions, and in whom at each monthly period there was sudden suppressio menses *following* the appearance of what the patient called her asthmatic complaint; of which, however, the symptoms were not those of regular asthma. They occurred at such times, and for a week or two afterwards, every other day, commencing with great coldness of the hands and feet, and headach; to which succeeded a peculiar difficulty of breathing, lasting all the day, and going off at night. The breath was not, in these attacks, as in asthma, suddenly drawn in and protractedly and sonorously expired, but the inspirations and expirations were short and panting, about forty inspirations being made in a minute; the pulse at the same time being very low and weak, and not more than *twenty* in a minute. There was a sense of weight, amounting to pain, in the sternum; pain in the region of the heart and between the scapulæ; and fulness and pain in the head; the face was flushed, and the eyes were protruded; a thick expectoration was described as sometimes inducing relief. We mention this case, however, chiefly because the symptoms of failing pulse, coldness, and orthopnoea, often led the friends of the patient to think that she was dying; and yet the complaint

has now for several months entirely disappeared under treatment calculated to improve the general health, to regulate the uterine functions, and to allay the great susceptibility of the nervous system. We were informed that in two or three members of the patient's family consumption had supervened on similar symptoms; but all medical men are aware of the doubtful nature of this kind of evidence.

In no class of patients is an irregular pulse more frequently observed: when it is first felt it is perhaps found to be very rapid; after ten or twelve beats this quickness subsides, but soon comes on again; and these alternations appear to be continual. Slight causes produce a more permanent excitement, during which the practitioner may be much misled; in a few days the excitement will be gone, and the pulse will be found languid and weak. If these caprices of the circulation are embarrassing when no serious disease is present, they become much more so in affections themselves important, as in acute inflammations, or in the commencement or course of continued fevers. Among the many modifications of the ordinary symptoms of fever by the hysterical constitution, we have remarked a singular inequality between the arterial pulsations and the respiration; the pulse being sometimes as slow as the ordinary respiration, and the respirations sometimes advanced to the ordinary rapidity of the pulse. These circumstances seem most common during the first three or four days of the complaint, and, occurring in any other than hysterical patients, would furnish ground for a very unpromising prognosis.

It is seldom that the hysterical respiration is unaccompanied with irregular or with hurried and vehement action of the heart; and it is particularly important to remember that an irregular as well as a very frequent pulse may be occasioned by many causes in an hysterical patient; by temporary causes, and by diseases unconnected with structural affection of the heart. We have known delicate females, during convalescence from a fever, repeatedly bled for palpitation really dependent on weakness, to the lasting impairment of a constitution already morbidly susceptible. It is to be said, however, that mere hysterical palpitation is occasionally attended with so much disturbance in the impulse as well as in the rhythm of the heart, as to make its resemblance to structural alteration of the organ such as even the stethoscope fails at once to disprove: the practitioner's chief assistance in the diagnosis of such cases must arise from his observation of the transient and occasional character of the symptoms, and from his knowledge of the patient's constitution.

The pulsations of the aorta are also in some hysterical cases greatly disturbed, principally as regards their force, which becomes so much increased that the patient complains much of the beating in the abdomen, and the practitioner himself is harassed with the fear of organic disease. In the course of fevers we have found this affection existing in a very remarkable degree, generally together with other irregular

symptoms; and the pulsation has been so vehement, and within a space so circumscribed, as very precisely to convey to the hand the sensation of a large, defined, pulsating tumour.

In different individuals, and in the same individual in different attacks, the disorder to which the name of hysteria seems justly given, (because such individuals always shew more or less of the hysteric character, and their various affections are more or less obedient to what may be called anti-hysterical remedies,) assumes shapes so various that it would be in vain to attempt to describe them all. There seems to be no function or organ in which irregularity may not be induced in an hysterical constitution; the irregularity occurring, and disappearing, or being overcome, with so much suddenness as to create a perfect analogy between such affections and the commonest forms of the disorder.

Thus in some cases the hysteric fit consists of temporary and partial loss of power, or a palsy of some of the voluntary muscles; sometimes of those of one limb; sometimes of those of the voice; and sometimes of all the voluntary muscles of the body, and the patient falls into a state of coma; is insensible; the face is flushed; the pulse beats regularly, even firmly; the respiration is calm and profound; and neither the sensibility nor the power of voluntary movement return for several hours. These cases somewhat resemble apoplexy, and cases are on record in which they have gone on to it: generally, however, they do not require active treatment. In the first case of this kind which we ourselves witnessed, a young woman fell down in the street, and we were at a loss to account for what seemed to us the rash prophecy of an experienced physician that she would recover in a few hours. These cases are mentioned by Whytt.* "Many hysteric women," he says, "are liable to be seized with faintings, during which they lie as in a deep sleep; only their respiration is so low as scarce to be perceived. Others, along with faintings of this kind, are affected with catchings and strong convulsions." A similar state may succeed to the more violent phenomena of hysteria;† and the functions of the heart and lungs may be so seemingly suspended, and the coldness so great, as to present the image of death. Pliny has recorded a case in which this state lasted seven days; and Lancisi mentions one in which a young woman recovered whilst the funeral service was performing. A more striking case occurred to Vesalius, who began to dissect a supposed dead body, to which life returned with the first application of his scalpel. Of the same kind, probably, was the case of a Lady Russell, in the early part of the last century, whose funeral having been postponed for a longer period than usual, afforded time for her happy

recovery, which took place while the bells were ringing for prayers; the supposed dead person exclaiming that it was time to go to church. Cases of this kind constitute M. Louyer Villermay's *third* degree of hysteria;* we see no shadow of reason for applying to them the name of hypochondriasis, as some have done;† perhaps they would be more properly classed under the head of syncope.

Instead of these comatose forms, there may be rigid spasm of several of the muscles, especially of the limbs; the legs and arms may be stretched out, the fingers strongly compressed on the palms, and the toes as strongly drawn up. This state may be varied by an occasional start, accompanied with a short and forcible expiration, and at length give way instantaneously, often to proper remedial means. The spasmodic state is described by credible authorities as having in some cases lasted for several weeks.

That a disorder capable of producing so many irregularities of function should occasionally produce a counterfeit representation of various maladies, and should singularly modify the course of others, is not surprising; but the deception is not limited to functional affections, being often extended to the imitation of organic changes. Diseases of the stomach, of the liver, of the intestines, of the bladder, and also of the heart, the lungs, and the brain, have thus been supposed to exist.

Some of the inconveniences which, in hysterical patients, are to be referred to a depraved state of the stomach and bowels, with great distention, have already been mentioned. It is to be added that prolonged constipation, continuing even for weeks, and sometimes the opposite state of obstinate purging, occur in such cases.

Hysterical women will complain of symptoms of obstruction of the gullet, of the rectum, and even of the vagina: and the urinary system is in them much and variously affected. Spurious symptoms of calculus in the kidney, the ureters, or the bladder, may arise and be of little consequence: dysuria, or even a suppression of urine may occur; but more frequently, as in other instances of nervous disturbance, there is an unusual flow of it, and sometimes a kind of false diabetes. These circumstances make such patients an easy prey to quacks and pretenders in medicine, by whom we have known them to be persuaded of the real existence of scirrhus formations, or other serious diseases with which they were not in reality affected.

Jaundice has supervened, in some cases, on hysteria. We have known pale and feeble women who were liable to acute and apparently spasmodic pain in the situation of the liver, and in a situation corresponding to the course of the ureter: these cases were connected with uterine irritation, and had been vainly subjected to various remedies administered for biliary and for

† *Hoffmann*.

renal disorder. Such cases are among the many in which bleeding and purging, and salivation, the ready instruments of coarse and indiscriminate practitioners, are daily productive of irreparable mischief.

Pains, of variable severity, often very severe, are among the distresses of the hysterical. A fixed pain in the forehead, and generally over one eye, which has been termed *clavus hystericus*, the sensation being that of a nail driven into the forehead, is very common. It is one of the many attendants of uterine irritation, to which, however, hysterical affections have been too exclusively attributed: we have known it disappear entirely during pregnancy, and again become troublesome a few months after delivery; and it is generally preceded by a sense of weight in the head, and an oppression in the throat; and is sometimes relieved by a flow of tears.

More severe and general invasion of pain in the head may come on, with much of the character of phrenitis; with senses morbidly acute, and small and rapid pulse; but without acute delirium, or red and injected eyes: the face also is very pale, and there is much hysterical agitation.

There is another painful affection, often also, we believe, connected with irregularity in the uterine functions, and attended with constipated bowels, in which the patient's chief suffering is fixed in the left side, below the mamma, and above the situation of the spleen. There is most acute tenderness without swelling; the patient cannot lie on the affected side; and the disease resists for months, sometimes for years, all varieties of treatment. Although we have said that these cases are often connected with uterine irritation, the depraved state of the appetite, occasional sickness, and obstinate sluggishness of the bowels, make us doubt the propriety of laying great stress on the uterine disorder. In these cases, or in most of them, there is some pain of the back, referred to the lowest part; and there is a tenderness of the spine, confined to the dorsal region. The pain of the sacrum is a common complaint with females in whom the uterus is unhealthy, and yet who are not hysterical, and who have no tenderness about the dorsal vertebræ; and neither the dorsal tenderness nor the sacral pain are present in many of the examples of the *clavus hystericus*, even when most clearly arising from uterine irritation. These circumstances, which we have very carefully verified, are incompatible with the uterine theory of diseases which we shall have to notice when speaking of the *causes of hysteria*.

The female breast is in some hysterical cases the seat of much pain, and is also enlarged and hard; so that the patient dreads the occurrence of cancer, although at an age when the practitioner has no apprehension of it. Dr. Darwall mentions a case, in his remarks on spinal irritation, where this was combined with tenderness of the three superior dorsal vertebræ, and all the symptoms were relieved by cupping. Pains of the limbs are not unusual, and they are now and then united with an impairment of

the motions of the hip or the knee, leading to a suspicion of disease of the joints. In very young but precocious females we have seen this curious complaint combined with strange affections of the sight and of the voice; of which one of the most remarkable instances that we remember occurred some years ago in the Edinburgh Infirmary: the subject of it was a girl of thirteen, and the lameness and partial blindness, and an appearance of fatuity, all disappeared under a steady application of Dr. Hamilton's purgative treatment.

Sudden and violent attacks of pain in the abdomen, with excessive tenderness of the surface, a quick pulse, and many symptoms which may be mistaken for those of peritonitis, sometimes take place in hysterical young women, yet without inflammation. It is to be observed that the tenderness, in all cases of hysterical pain, is most felt on slight pressure, and is often evinced on the gentlest touch; which is not commonly seen in instances of internal inflammation.

The most severe examples of colica which we have met with have been in hysterical women; cases of excruciating pain, not yielding entirely for many days, during a great part of which time the cries of the patient have disturbed the whole house. These cases have been denominated flatulent or hysteric colic. In these cases, if the extreme tenderness on slight pressure is present, firm pressure is borne much better, and perhaps gives relief: the tongue is often clean, or has not the whiteness so general in enteritis; there are also intervals of relief from suffering, during which the patient's voice is calm, and the pulse not much quickened, or is sometimes slower than usual, without any sharpness, and even very low. Such attacks are often relieved by the dejection of copious, dark-coloured, and offensive stools.

Inequality in the regulation of the animal temperature is another troublesome part of hysteria. Fits of coldness and of oppressive heat succeed each other; or the feet are cold and insensible to the hottest fire or to very hot water, whilst the head and face are burning, in which case there is commonly some delirium. A feeling of coldness running down the spine, which is familiar to nervous persons, is often present in the hysterical.

We cannot recollect to our mind a hysterical patient whose sleep was generally tranquil and undisturbed: many have complained of prolonged and distressing wakefulness, their nights being often passed in a state of perfect vigilia, and at other times rendered uncomfortable by restlessness and distressing dreams. Yet it has always appeared to us as remarkable, that, unlike epilepsy, the hysteric attack does not usually come on in the night, or after sleep.

Many pages might be filled with accounts of singular forms of disease, productive, according to the degree of information possessed by the attendants, of more or less wonder and perplexity, which have been observed in all ages, and which might justly be classed with hysteria. From the irritations occasioning mere rest-

lessness, yawning, and what are called "the fidgets," up to the most capricious and violent disturbance of different parts of the system, there seems to be nothing strange or odd which hysteria has not at times exhibited. Among these curious phenomena may be mentioned a disposition on the part of the patient to repeat some unmeaning syllables from morning to night, or during several hours every day; or, whilst lying otherwise motionless and seemingly insensible to outward impressions, to sing loudly and for a length of time a few particular notes, repeating them a thousand times. Pious ejaculations, hallelujahs, and snatches of hymns, we have thus heard vociferated to the excitement of a mixture of awe and amusement in those around the patient, who will sometimes seriously enquire whether the physician does not believe the patient to be bewitched.

Dr. Parry's notes* contain the case of a young lady of fourteen years of age, in whom menstruation had commenced a year before, and who, after being present at an exhibition of fireworks when but recovering from slight indisposition, complained of weariness and giddiness, and pain of head; on which ensued spasmodic motions of the hands and fingers, and convulsive actions of various parts, which continued for some hours. Two days afterward the attack returned, and, as she lay on her back, rather towards her right side, she threw the left arm and body backwards at measured intervals, exactly keeping time with two or three notes which she sang out with a strong and clear voice; and this scene was repeated every day from eleven to three at noon, and from eight to ten at night, leaving her much fatigued, after which she slept well. She was fond of music, and could both play and sing, but could assign no reason for the particular song so often repeated, but that "it was irresistible." These attacks were occasionally repeated for ten or twelve days more. When the treatment pursued began to take effect, the song began to disappear, but she was uncomfortable, or had an attack of headach, or cried and made pale urine at the usual hour of the attack. Dr. Parry succeeded in checking the convulsive motions by compressing the carotid artery: the patient was bled, leeches were applied, and purgatives and nitrate of potass and squill were administered.

The tendency of the phenomena of nervous disorders to return at stated intervals, although often observed, seems to have been forgotten in the instance of some of the most unusual forms, and cases of this kind have been erroneously classed, from the mere circumstance of the periodicity of the symptoms, with ague.†

Dr. Bright has given cases of hysteric hiccup, and of spasmodic exclamation, and of hysteric dysphagia.‡ In the latter case the introduction of the probang induced an hysteric fit,

which was immediately followed by hysteria in several females in the same ward; thus illustrating the effects of *imitation*, which we shall have to speak of among the causes of this affection.

The name of simulated pregnancy has been given to some cases of hysteria, in which the abdomen enlarges gradually, sickness occurs, and so many signs of an impregnated uterus are present, that time alone can solve the doubts they raise. The catamenia are suppressed, the breasts are tumid, and there is pain in the back. Mr. Tate says, of these cases, "in what this engorgement consists, I am utterly ignorant: that it is not a mere accumulation in the colon, I know; and that it is substantial, I am equally sure."* It is, we apprehend, a mixed state of vascular fulness and tympanitic distention.

Dread of water, the disengagement from the body of electrical sparks, the occurrence of spontaneous emphysema, and the phenomena of somnambulism, have been observed in the hysterical; and cases of misplaced *senses*, which are entitled to little credit. We have dwelt sufficiently on the anomalous forms of the disorder in some degree to prepare the inexperienced practitioner for the singular appearances which hysteria often assumes. The older writers, whose observations were often made in religious houses for the reception of women devoted to celibacy, have recorded other examples, some of which we shall have occasion to refer to.

We shall not pretend to give any explanation of the surprising revelations or presentiments, or shadows of coming events, which have been said at times to be associated with the hysteric paroxysm. When the small portion of truth which such relations contain is separated from the fancy, the fable, and the fraud with which it has been invested, it may perhaps be rendered intelligible by the consideration that extreme excitement of the brain may lead in these states of disorder, as in troubled and vivid dreams, to combinations of images, and to probable suggestions concerning the course of events past or to come, which appear to a sober and healthy mind, unacquainted with such wild excitement, as too extraordinary not to be supernatural. Concerning animal magnetism, connected as it is with this part of our subject, we shall only express our hearty disbelief of most of the circumstances related by its supporters, and our conviction that the rest admit of explanation without having recourse to the principle the magnetisers so anxiously desire to establish.

Amidst such general disorder, the nervous system being so frequently, perhaps so invariably involved, the functions of the brain often become deeply affected. Increased susceptibility to impressions, celerity of movements, and capriciousness of motives, strongly characterize the hysterical female: her countenance indicates the mutability of her feelings; and when the constitution is intensely imbued with these characters, the most amiable sentiments are seen to be readily converted into jealous and

‡ Reports of Medical Cases, vol. ii. p. 457; cases ccxi, ccxii, ccxvi.

fierce passions, and all sense of humanity to be lost in the gratification of cruel and remorseless impulses. Sydenham, whose industry and sagacity are equally discernible in all his writings, has left us a graphic picture of these effects, and his testimony will sufficiently assure the reader of their reality. "Upon the least occasion also," he says, "they indulge terror, anger, jealousy, distrust, and other hateful passions; and abhor joy, and hope, and cheerfulness, which, if they accidentally arise, as they seldom do, quickly fly away, and yet disturb the mind as much as the depressing passions do; so that they observe no mean in any thing, and are constant only to inconstancy. They love the same persons extravagantly at one time, and soon after hate them without a cause; this instant they propose doing one thing, and the next change their mind, and enter upon something contrary to it, but without finding it: so unsettled is their mind that they are never at rest." This description was perhaps intended by Sydenham to comprehend the hypochondriac character; and yet, although not to be taken as a general representation of the hysterical mind, we have seen it so exactly exemplified in the hysterical as to be greatly struck with the truth of this great physician's painting. Cases of this kind approach near to insanity; and, indeed, a mind subject to the violent agitations incidental to the hysteric constitution cannot be considered as perfectly sane. We would here beg to insert a caution to which the young practitioner cannot pay too much attention. We are inclined to think that cases of hysteria, in which the mind was principally affected, have occasionally been treated as cases of simple mania, and the patients placed in confinement with lunatics. Nothing more likely to have the most unfortunate effects upon the patient could possibly happen; and no care can be too great to avoid a mistake which would in all probability render such a case incurable and hopeless.

The disposition to dread the approach of disease on the occurrence of slight feelings of an unusual description has frequently been observed in those disposed to mania, and is a leading feature in cases of hypochondriasis: it is also seen in some instances of hysteria. The physician is hastily summoned as if to a severe disease, and finds no real cause existing for the patient's alarm. A morbid susceptibility of all parts of the nervous system disposes, in them, all parts to diseased, or at least to undue impressions; to false or diseased sensations, and to irregular or diseased actions. Any function consequently may, in the hysterical constitution, be readily disordered; as the respiration, the circulation, the digestion of food: any part may be affected with pain and the usual symptoms of confirmed disease; and, at length, the parts thus affected may really become the seat of inflammation or other disorder, and undergo a change of structure. For these ultimate results of hysteric disorder the physician should in all severe cases be prepared.

As the deeper shades of hysteria border upon or enter the confines of insanity, so the

lighter comprehend several varieties of constitution characterised by increased susceptibility, and in which, some time or other, it is found that peculiar impressions evoke some of the hysteric phenomena. With many of these cases the guardians of education are more directly concerned than the medical practitioner; and the principles of their management may be gathered from the valuable observations contained in the article *PHYSICAL EDUCATION* in the present work. It is quite certain that the unhappy temper and violent irritability of hysterical females, combined with their constitutional tendency to the hysteric paroxysm, is in some instances sufficient to bring on, almost at the will of the patient, attacks which occasion much concern to their relatives or friends: we have seen undoubted instances in which a temporary loss of muscular power, a singular diminution of the action of the heart, and an inability to speak, but without loss of consciousness, originated in the desire of a self-willed individual to distress the spectators, or to overcome opposition to some wayward desire; as if the wish to feign an attack brought on a real paroxysm. Frank mentions similar cases, and others against which it is very necessary that a young medical man should be on his guard.*

It occasionally happens, however, that individuals whose education has long been completed, and whose temper and intentions are blameless, are driven by the intolerable sufferings of a highly susceptible nervous temperament to consult a physician; who will be more likely to be of service to them in proportion as he regulates the treatment of them according to the principles of the prevention of hysteric paroxysms. Rank, fortune, and reputation are insufficient to counterbalance the evils attendant on such a temperament; and, unfortunately, those who are most subject to its distresses seldom possess the firmness and perseverance indispensable to a perfect cure.

Modifications of disease by hysteria.—It may be supposed that a disease capable of simulating so many others may modify some rather remarkably. The most important of its modifications are seen in the course of fever. Rivière, Baillou, and even Morgagni, entertained the idea of a distinct hysteric fever as a species; but M. Loyer Villermay justly considers such cases as having been nothing more than examples of anomalous symptoms belonging to fever. We have seen nothing in practice to make the opinion of the former authorities credible: it seems to have been purely founded on theory. But the incipient symptoms of fever, its progress, and the circumstances of convalescence, may be much modified by the hysteric constitution. Irregularity in the respective frequency of the pulse and the respiration; an hysteric fit, of the comatose description, ushering in the febrile stage; a disposition to delirium in a state bordering on sleep, yet in which the patient is conscious of what is passing around her; a very singular exaltation of the *tone* of the voice,

* *Præceps Medicæ Universæ Præcepta*, cap. xiv. § lxxii. 22.

without increased loudness; a state approaching to catalepsy, but with consciousness remaining; sudden and unexpected, but not always complete recovery; and transient attacks of mania; we have on several occasions observed: and in almost every instance in persons living an easy and indulgent life, and, with the exception of one or two cases in upper servants, seldom among the poor.

In the course of a severe attack of fever in a young lady at school, great alarm was one evening occasioned by the supervision of what was supposed to be *croup*. There was laborious breathing, a loud croupal sound, and great distress apparently existing in the throat, almost amounting to suffocation; and the patient was unable to speak. Similar attacks recurred every night for three or four nights, lasting for an hour or two. These gave place to paroxysms of severe spasm in the stomach, occurring with equal regularity; and these disappeared on the supervision of what might be termed *paroxysms* of sleep, which came on with a febrile exacerbation every afternoon: in the midst of cheerful conversation, intended to make the patient forget her sleep, she would drop instantaneously into a state of sleep the most profound, lasting however, generally, not more than a quarter of an hour, sometimes continuing about an hour. On awaking from this sleep the spasm of the stomach sometimes recurred, and there was occasionally a disposition to the croupal phenomena. This was a tedious and severe case, and excited great alarm in the patient's friends, although there was never any great appearance of danger in the estimation of a medical observer. On the importance of remembering that these and other odd accidents may occur in fever it is quite unnecessary to dwell. Few things are more gratifying to the physician than to be able, relying on his knowledge, to be calm and assured when all around him are in a state of agitation and dismay.

The patient who was the subject of the above case had been some months previously affected with *rubeola*: the eruption came out, and seemed to be disappearing at the usual period, when it suddenly broke out anew, and to such an excessive degree as to make it impossible to recognize the features of her face: whether or not this peculiarity was also connected with the hysterical constitution we cannot take upon ourselves to determine.

In another case of an hysterical young lady we have happened to witness two attacks of continued fever, with an interval of four years between them. On each occasion very severe hysterical symptoms have come on, recurring every day, or every other day, or observing longer periods, principally in the form of short spasmodic agitations about the chest and neck, followed by a disposition to crying, with more rapid agitation of the chest, apparently connected with irregular contractions of the diaphragm: a feeling of suffocation often ensued, sometimes with a temporary suspension of respiration, deep redness or blueness of the face, often only in spots or patches. The addition of such symptoms to the usual disorders of the

febrile state constitutes a state of extreme and complicated disturbance and suffering, in which it is difficult to distinguish the effects of the fever from the hysterical accompaniments. Pain in the head, pains in the limbs and back, difficulty in moving, costiveness, dysuria, and many other symptoms, exist in such cases at the same time; and there is usually much tenderness of the spine, sometimes with, sometimes without uterine irregularity.

It would be impossible to enumerate the modifications which may take place in other diseases: any unusual assemblage of symptoms, or remarkable inconsistency in their respective severity or order, may awaken inquiry, and will generally be found to depend upon some degree of the hysterical character in the patient. The development of hysterical symptoms in the course of other maladies is occasionally dependent on weakness, either produced by the continuance of the disease or by certain accidents in its progress, or by particular kinds of treatment. Thus, in the debility of the stage of convalescence from fever, and after hemorrhage, and after parturition, and after the employment of very free bleeding, the occurrence of unmeaning laughter or tears, and other parts of the hysterical attack, are not at all uncommon, and always require some attention to their cause.

Whether hysteria has supervened upon some other disease, mixing with and modifying it, or has been in any other way produced, it has a tendency, when severe, long-continued, or frequently recurring, to produce further mischief, and new complications. Inflammatory actions, for instance, take place at or near the extremities or origin of previously irritated nerves; or, as some authors have expressed it, the disease of the system of innervation becomes combined with disease of the vascular system; and morbid changes take place in the brain, spinal marrow, nerves, or some of the organs supplied by them. In the course of a long hysterical disorder, and yet more readily in the course of a fever in an hysterical patient, the tenderness of the spine may become excessive; and disordered sensations and impaired powers of motion will indicate that something more exists than mere irritation. These symptoms may disappear as the patient recovers strength; but they sometimes attain a degree of intensity requiring especial attention, and even inducing an apprehension of danger. The spinal tenderness in these cases is very different from that excessive sensibility to the slightest touch which some hysterical patients evince during the hysterical attacks, and which is of a very evanescent character, often alternating with, or perhaps accompanied by, an equally morbid sensibility of the limbs, or of the articulations.

Hysteria is one of the disorders of which the consequences are much less serious, as far as the life of the patient is concerned, than its more violent phenomena would lead an inexperienced observer to fear. It can hardly ever, perhaps, be considered as in itself fatal. The secondary diseases to which we have already

said it may lead may be fatal. Congestion or inflammation in portions of the brain may occasion death; or the patient may die apoplectic. M. Louyer Villermay has quoted a case of a young woman of fifteen, in whom a most violent hysterical attack ensued on the sudden suppression of the catamenia in consequence of terror. The paroxysm continued more than two days; *nothing was done for the patient's relief*, and she died on the third day, being only fifteen years of age. The patient had complained of a feeling of suffocation, as if a tight collar was fastened round her neck; the hypogastric region was tumid; she could not swallow; she was convulsed; the action of the heart was tumultuous; in short she had had every symptom of violent hysteria. On dissection, the stomach was found contracted, and strongly incurvated, (*fortement revenu sur lui-même*); the left cavities of the heart were empty, as were also the pulmonary veins and the arteries; whilst the right cavities, the pulmonary artery, and the veins, were gorged with black blood, chiefly coagulated. The cerebral veins and the sinuses of the dura mater contained much blood; but there was no appreciable alteration of the brain or spinal marrow, or their coverings, or in the nerves. The ovaries were very large and very firm, and enveloped in a partially transparent tunic, (*une sorte de tunique albuginée, mais transparente dans plusieurs points*). In the interior of the ovaries there was a large collection of round vesicles, filled with an abundant mucous fluid, which required for its escape the separate puncture of each vesicle.*

The same author is one of the very few writers on hysteria who have especially devoted a section to the appearances found in fatal cases. He adduces the testimony of Riolan, Blancardus, Binninger, Vesalius, Diemerbroeck, and Morgagni, as to morbid appearances in the ovaria more or less resembling those mentioned in the above mismanaged and most unfortunate case; without, however, concluding that such alterations, or any changes in the state of the uterus, are constant.

We spoke, some pages back, of the super-vention of jaundice on hysteria, but this, like the occurrence of phthisis, can only be looked upon as an accidental complication. It may sometimes, however, happen that the patient, worn out by the long continuance of the malady and repeated paroxysms and frequent agitations, may become peculiarly liable to the supervention of the last mentioned disease; or may become affected with a slow fever, the body gradually wasting, and the strength decaying, and a premature death at length ensuing.

But among the peculiarities of the hysterical constitution, are to be reckoned some unexpected recoveries from states which seem to furnish an utterly hopeless prognosis. Of such singular cases and their termination we generally have an outline in the expression which all must on some occasion or other have heard employed, that such a patient fell into an odd state, and

remained so for a year or longer; that nothing could be made of her case, and that at last she got better, nobody very well knew how or why. These curious reprieves are sometimes from what has appeared to be atrophy, or phthisis, or paralysis; but they have, we believe, occurred after a strong image had been presented of other incurable diseases and of impending death. M. Georget very properly guards the practitioner, therefore, against forming and pronouncing too hasty a prognosis in all cases of hysteria; observing that not only do such occasional recoveries sometimes unexpectedly take place, but that the course of diseases of a fatal character is often much more prolonged in the hysterical than in those of a different constitution.*

Hysteria in males.—We have met with a few instances which we consider to have been decided examples of hysteria occurring in males. The subject of one was a gentleman who had devoted himself with too great intensity to his studies, being designed for holy orders. After leading a life of great retirement at Oxford, and, in opposition to his temperament, of strict chastity, his mind became irritable, and he could not obtain refreshing sleep. On several occasions he was suddenly seized with violent sobbing, gasping, and anhelation, attended with a fear of immediate death by suffocation. During these attacks his face was flushed, the carotids pulsated strongly, and the heart was much disturbed; but he retained his consciousness. We were also acquainted, some years ago, with two gentlemen who were singularly intemperate in drinking, and in both of whom excess sometimes induced fits of sobbing and crying, with palpitation, a weak pulse, a loss of muscular power, great dyspnœa, painful constriction of the chest, and fear of impending death. In cases of melancholia we have found the patients complain of violent agitation of the stomach and bowels, with a disposition to shed tears. We have known the silence of a sick house unexpectedly disturbed by the uncontrollable and loud laughter of a patient dangerously ill of fever. Very decided hysterical symptoms came on during convalescence from fever in a boy who was a patient of the University dispensary: his mother was much troubled with hysterical fits; the boy's affection was evidently caused by debility, and disappeared as he regained strength. Sydenham relates the following case, in which the cause and the result were the same. It deserves to be quoted, both as an illustration of the practice of that great physician, and on account of the important relation of such cases to the theory of the causes of hysteric disorders in general.

"I was called," says he, "not long since to an ingenious gentleman, who had recovered of a fever but a few days before. He employed another physician, who had bled and purged him thrice, and forbid him the use of flesh. When I came, and found him up, and heard him talk sensibly on some subjects, I asked why I was sent for; to which one of his

* *Traité des Maladies Nerveuses*, p. 70.

* Vol. ii. p. 288.

friends replied, if I would have a little patience I should be satisfied. Accordingly, sitting down and entering into discussion with the patient, I immediately perceived that his underlip was thrust outward, and in frequent motion (as it happens to fretful children, who pout before they cry), which was succeeded by the most violent fit of crying I had ever seen, attended with deep and almost convulsive sighs; but it soon went off. I conceived that this disorder proceeded from an irregular motion of the spirits, occasioned in part by the long continuance of the disease, and partly by the evacuations that were required in order to the cure; partly also by emptiness and the abstinence from flesh, which the physician had ordered to be continued for some days after his recovery, to prevent a relapse. I maintained that he was in no danger of a fever, and that his disorder proceeded wholly from emptiness; and therefore ordered him a roast chicken for dinner, and advised him to drink wine moderately at his meals; which being complied with, and he continuing to eat flesh sparingly, his disorder left him."^{*}

This subject is of so much importance, particularly as regards the alleged dependence of all cases of hysteria on some disorder of the uterus, an opinion which cannot be admitted without materially influencing our practice, that we shall quote one or two more examples from authorities which cannot be called in question.

In Dr. Whytt's work on Nervous Disorders, which has already been more than once referred to, and which deserves, even at this day, an attentive and entire perusal, the following case is related, the connection of which with hysteria of the periodical character appears unquestionable.

"A boy of ten years of age, of a very sensible nervous system, who, in December 1747, had been seized with a palpitation of his heart, fell from his horse about the beginning of January. From this time the palpitation left him; but in a few days after he was attacked with a violent headache, returning sometimes once a day, at other times only every third or fourth day. During the fit his pulse became smaller and quicker, and often intermitted; his feet were cold, but, by the violence of the pain, a plentiful sweat broke out and relieved him. As these headaches continued to increase, the patient lost his stomach and flesh, and looked pale. By the use, chiefly, of an electuary of the bark and valerian, in less than three weeks the pain of the head abated greatly; but his appetite grew worse, and he often complained of a nausea. These symptoms, however, were all removed in four or five days, by some warm stomachic and cordial medicines, but were succeeded by an

intolerable pain across the middle of his belly, which, in the space of eight days, returned five or six times, and not only affected his pulse, as the headache had done, but sometimes occasioned a difficulty and pain in making water. This pain no sooner left his belly than the headache returned with greater violence than ever, so that the boy used to faint in some of the worst paroxysms. It had no certain periods, coming sometimes twice a day, sometimes only once in two days, and was attended with a sense of suffocation from wind, and a lump in his throat. He was easiest in the night, when he slept or lay quiet, but any considerable motion of his body always raised his headache. Before the fits he was observed to be uncommonly lively, and disposed to laugh. On the 21st of February, at two in the afternoon, he was seized with fits of involuntary laughter, between which he complained of a strange smell, and of pins pricking his nose: he talked incoherently, stared in an odd manner, and his complexion changed to a livid colour; immediately after he was seized with convulsions, and then fell into a fainting fit, which lasted near half an hour."

The remainder of the case may be abridged. Purulent matter was subsequently discharged from the nostrils and the right ear, with some alteration in the situation of the pain, which shifted to the back of the head, and then to the left side of the abdomen, "between the short ribs and os ilium, confined to a space little larger than the breadth of a shilling. This pain was often so severe as to make him ready to faint; sometimes it shifted, and then he was seized with fatiguing fits of involuntary laughter."

This case appears to have resembled some of those mutable examples of the disease which are more commonly met with in females, and in which the relief given to one affection is but the signal for the raising up of another, constituting cases comprehended in Dr. Marshall Hall's excellent description of "Disorder of the General Health."

The fact of hysterical disorders appearing in male subjects is supported also by the highly respectable testimony of Dr. Ferriar.* "Men," he says, "are frequently attacked by complaints which approach to the hysterical type. In the following instance a young man was affected with regular hysteric fits, in consequence of continued vexation and anxiety. In spring, 1789, I was desired to visit a patient about seventeen years of age, on account of fits with which he had been seized a few days before. I was told that they began with great dejection of spirits, sighing, and uneasiness about the præcordi. He then became apparently insensible, but groaned much, and did not recover for a considerable time. He relapsed frequently, from slight causes, and often had three or four fits in a day. He said that he felt the globus hystericus at the approach of each paroxysm, and he said that he retained his senses, in some degree, to the termination of

* Op. cit. p. 381. Cases of hysteria in men are also mentioned by Louyer Villermay and by Georget: the latter quotes the words of Piso, (or Lepois, an author of the 17th century, whose name is latinized according to the custom of the time,)—*Hysterica symptomata omnia fere viris cum mulieribus communia sunt. Caroli Pisonis Select. Obs. et Consil. &c.* We have no opportunity of referring to the original.

* Medical Histories and Reflections, vol. 1, p. 128.

each. His pulse was weak and hurried; his tongue somewhat foul; and his countenance timid. His evacuations were natural. I do not recollect the particular nature of his employment, but it was of a sedentary kind. After clearing his stomach by an emetic, I directed some pills to be made up composed of opium and assafoetida, and to be given in such a manner that he took half a grain of the former and four grains of the latter every hour previous to the approach of the coming paroxysm. On the first day of taking the pills the fit came on, but in a slighter degree. The next day he was ordered to begin at a greater distance from the usual time of the fit. He took by this means three grains of opium, and more than a scruple of assafoetida. The paroxysm was effectually prevented by this dose, without producing the smallest uneasiness to the patient. Two of the pills were given at bed-time for a few nights afterwards, and the cure was finished by administering tonics."

In the above case the evidence of the *juvantia*, taken together with that of the symptoms, seems to leave no doubt of its being an example of hysteria; and we shall not dwell longer on this point, except to refer to a remarkable instance of temporary loss of voice from hysteria, occurring in a recruit in the East India Company's service, and related by Mr. Watson, the surgeon of the ship on board of which the patient was a passenger.* The subject of this case was a strong healthy man, who complained first of giddiness and headach, was then convulsed, and had some of the symptoms of epilepsy, as distortion of the muscles of the face, and discharge of frothy matter from the mouth. After an interval of some hours these symptoms returned, with alternate laughing and crying, spasms about the throat, and inability to speak, although he was perfectly sensible. After being twice bled, and having a blister applied to his head, and taking some active purgative medicine, he recovered his speech, in about forty-eight hours. The account he then gave of himself was that he was prevented from speaking by a tightness in his throat, which felt as if something was in it. Mr. Watson observes that but for the supervision of those symptoms the case would have been considered as epilepsy. It is worthy of remark that another case occurred on board of the same ship about a fortnight afterward, of which the subject was an artillery-man, who, however, recovered his speech on the following morning. Mr. Watson, in conclusion, quotes Dr. Trotter† as saying, "We found not a few of the cases sent to the hospital-ships subject to very frequent fits of hysteria; and where this singular affection occurred, with as much violence of convulsion as we have ever marked it in female habits, attended with globus, dysphagia, immoderate risibility, weeping, and delirium."

These cases and authorities are, we think,

sufficient to set the question at rest. The cases of hysteria in men must, however, still be considered as rare; although we have met with few observant practitioners who have not answered our inquiries on this point by stating that they had seen one or two examples very much resembling it.

Diagnosis.—The importance of not pronouncing serious diseases to exist which are only simulated is almost equal to that of not overlooking serious disease when it is really established: in the latter case the patient's life may be sacrificed to neglect; in the former it may be destroyed or endangered by unnecessary activity. For these reasons we have already insisted on the propriety of every opportunity being taken to enlarge the practitioner's knowledge of the varieties of hysteria; and it is equally necessary that he should keep in mind the tendency of all the violent forms of this disorder to pass to severer and more permanent lesions of function, and even to lesions of structure. Fortunately, the diagnosis of the most important cases is commonly the easiest; as it is more easy to recognize and verify the symptoms of severe diseases, the existence of which may be apprehended. Cases, however, will now and then present themselves requiring the greatest degree of circumspection, and the circumstances in which the patient is placed are often of a nature to produce agitation and haste, of which the effects are most pernicious. It is only by a careful study of the symptoms of diseases of the brain, lungs, heart, intestines, liver, kidney, and other important organs, and by a scrupulous comparison of *all* their symptoms with the case before him, that the practitioner can escape deception; for many symptoms may be present without real disease, and sometimes serious disease may be present and yet only partially represented by the ordinary symptoms. The slightest admixture of hysterical phenomena forms a sufficient ground of suspicion, and any great departure from the ordinary course and effects of maladies should alone awaken great vigilance. Great mutability of symptoms, or intervals of ease alternating with symptoms of much violence, will generally declare the nature of the case at once. There is, in truth, nothing so difficult to be written, or to be learnt by reading, as diagnosis, in this as in all other instances; but habits of caution, of tranquil observation, and of careful consideration, may be learned by every practitioner of ordinary capacity; and, thus disciplined, he will seldom be deceived, even by hysteria.

To distinguish hysteria from epilepsy, a disease generally so much more formidable, is of such great importance that almost all who have treated of these diseases have attempted to lay down certain marks of difference between them. Yet M. Louyer Villermay informs us that M. Pinel, on instituting an examination of the patients detained in the Salpêtrière as epileptic, found a great number of women, several of them young women, who were only hysterical, and yet who were separated from

* Edin. Med. and Surg. Journal, vol. xi. p. 303.

† Medicina Nautica, vol. ii.

their families and from society.* To pronounce a young female patient epileptic is often in its consequences only second to pronouncing her insane: the disease is considered to be incurable, to have a tendency to destroy the understanding, and to be transmissible to offspring; none of which terrible evils are associated with the name of hysteria.

The attack of hysteria is commonly less sudden and less violent than an attack of epilepsy. Epilepsy is often ushered in by a loud cry; the patient falls violently to the ground; the muscles of the face are severely convulsed; the eyes are distorted; the tongue is protruded and bitten, and frothy saliva forced out of the mouth. In hysteria there is seldom any incipient cry, although the patient may cry or laugh during the paroxysm; the patient, except in the comatose variety, does not fall suddenly, but, feeling the approach of the fit, is usually attacked after sitting or lying down: the muscles of the face, and the eyes, are usually tranquil, and the face is generally flushed, whereas in epilepsy it has often a ghastly paleness. The hysteric patient does not protrude or bite the tongue, nor is there a discharge of frothy saliva. The epileptic patient does not laugh or shed tears, but is in a state of fixed and intense agony; neither is globus a sensation known to him. After the fit the epileptic patient generally falls into a heavy sleep or sopor. During the paroxysm of hysteria the pupils of the eyes are commonly sensible to light, which is not the case in epilepsy. After the paroxysm the hysteric patient often remembers all that has passed, which the epileptic does not. It may be added that epilepsy is most common in men, in whom hysteria is rare; and that the character, habit of body, and history of the cases, will frequently afford instructive circumstances of difference.

It was Sydenham's custom, he tells us, always to enquire whether any particular disorder about which he was consulted in women did not chiefly attack them "after fretting, or any disturbance of mind;" and, in an attempt to make a difficult distinction, such an inquiry, and others of a similar tendency, will sometimes not be found superfluous.

"The patients and the nurses at the Salpêtrière," says M. Georget, "attach the principal importance to the three following characters of epilepsy: the want of precursory symptoms; the complete loss of consciousness; and the distortion of the mouth and state of the eyes. They say of a case of hysteria passing into epilepsy, that the patient begins 'to laugh on one side' and 'to turn her eye,'—*à rire de côté, et à tourner l'œil.*" The cases here pointed to, cases of mixed epilepsy and hysteria, are certainly now and then met with; and their character is of course only to be determined by the assemblage of symptoms in each.

The remarkable impression left on the countenance by successive attacks of epilepsy is familiar to all medical observers: there are few

instances in which the face presents no trace of the storms which have passed over it and over the whole frame. The same protruding eye and dulness and passiveness of look are not seen in the hysterical; and when the hysteric character is at all imprinted in the physiognomy, it is rather to be read in a changeful expression, and unquietness and want of repose in the face, which it is not easy to describe.

Causes.—A mere inspection of the various forms of hysteria would, one would suppose, be of itself sufficient to shew that all were not very likely to arise from one kind of cause; but that, if all the causes are admitted to act on the brain, and through the nervous centre on the parts affected in the paroxysm, still the seat of the primary irritation is various. But, perhaps from the disposition in the human mind to avoid a complication of difficulties, many authorities have ascribed all the varieties and examples of hysteria to some one irritation, as, for instance, to irritation of the uterus. A comparison with one another of the examples of this disorder which have fallen under our own observation leads us to reject all such exclusive views of their origin, and to believe that the causes of hysteria may consist of any circumstances capable of producing a particular excitement of the nervous system, or certain portions of it, which excitement leads to all the other phenomena. Of the primary irritation we should say that by far the most common seat is the uterus and the intestinal canal; but that sometimes the irritation is such as primarily to affect the whole nervous system, as plethora, anæmia, atmospheric changes, and mental impressions. Such being the exciting causes, of the predisposing cause we can only say that it is a peculiar and constitutional susceptibility to impressions, with an inherent disposition to institute certain actions affecting particular organs and functions, the object of which actions seems to be the relief of the nervous system, sometimes by the equalization of the circulation. We are not more able to explain the form of these actions, or the hysterical paroxysm which supervenes on the cerebral excitement springing from the primary irritation, than we are to explain the ordinary phenomena of laughing or crying, arising from a similar cerebral excitement originating in impressions primarily affecting the mind.

That certain states of the uterus, causing peculiar sympathies in different parts of the frame, are the causes of hysteria, is an opinion of great antiquity, and has been supported by nearly every observer from the time of Hippocrates, who has often been quoted as saying that a woman's best remedy in this disorder is to marry and bear children. Whoever considers the sympathies excited by the changes which the uterine system undergoes at puberty and during pregnancy, and at the cessation of the catamenia; the altered form and character of the young female; the capricious wishes and taste, or *longings* of the state of utero-gestation; and the morbid actions of what is called the "change of life;" will without difficulty

* *Traité des Maladies Nerveuses*, vol. i. p. 117.

admit that the hysterical phenomena, bodily and mental, may very probably be called forth by peculiar conditions of the same dominating system in the female economy. Extensive experience confirms such an opinion; and the occurrence of hysteria in early life, or after marriage, or at a later period, is so often observed in individuals in whom there are evident signs of the activity of the uterine system, as to connect the two circumstances together in the firmest manner. Precocious development and disappointed hopes on the one hand, and excessive indulgence, or marriages immature or physically disproportionate on the other, are causes of hysteria of which every practitioner finds illustrations within the circle of his own practice; as well as of the disappearance of hysteria after a long-desired marriage, or when means are taken to prevent hurtful excesses. In some females hysteria supervenes on puberty, continues to be more or less troublesome until the period of cessation, and then disappears. In others, as was remarked by Hippocrates, it disappears during pregnancy. And in the few cases in which death has seemed to supervene on simple hysteria, disease, as has already been mentioned, has been discovered in the uterine appendages. We cannot therefore be surprised to find that many ancient and modern writers have considered hysteria as being solely a manifestation of a disordered uterus; and that various theoretical notions have been engrafted, in the different periods of physic, upon this too exclusive opinion; some of which have been disproved by the progress of anatomy and physiology, such as the dependence of hysteria on the ascent of vapours from the womb, and of the symptom of globus on the ascent of the womb itself. To such notions we now only allude as curious remains of an age delighting in medical conjectures, and unpossessed of means of obtaining more accurate knowledge. But the facts on which such theories and practices conformable to them were built, yet remain; for nature and the laws of the human body are yet the same. In a susceptible female temperament, and in the unmarried state, the system of reproduction, every change in which involves many other changes, acts strongly on the system at large, and in certain circumstances disorders all the functions of the body and the mind; the digestion of food, the circulation of the blood, the judgment, the affections, and the temper; and in many of these cases all the mischief is removed by marriage, which, by awakening the natural functions and normal sympathies, allays the whole series of irritations or morbid actions. There can, therefore, be no reasonable doubt entertained that in a great many cases—perhaps we might say in the majority of cases—the cause of hysteria is some more or less discoverable irritation existing in some part of the uterine system, exercising its wide influence on the susceptibilities of a nervous system by nature too easily affected by all impressions. We may perhaps agree with M. Louyer Villermay to call this “a nervous disturbance, an exaltation of organic sensibility of this organ;” but

we must add that his statement of the proofs of such a condition, drawn from the asserted state of the hypogastric region, of the vagina, &c. &c.* however consonant with the older doctrines, has an air of inefficient practical observation which would almost lead us to doubt, with M. Georget, whether or not he had actually ever seen a case of hysteria. The very abuses to which such a theory has led and must lead, and the unjust suspicions to which it would often give origin, are sufficient to draw even a minute attention to its foundation.†

As far as the writer's experience has extended, and from observations made whilst recording very numerous cases, comprehending nearly all the forms of amenorrhœa, hysteria very rarely supervenes on the amenorrhœa of *young women*; and, compared with its frequency *after* the age of twenty, very seldom appears *before* that time. In cases, also, in which the hysteria has most plainly depended on the suppression of the catamenia, the comatose form of the paroxysm has appeared to be the most common. We have frequently found hysteria co-existent with chronic leucorrhœa and repeated attacks of menorrhagia, in circumstances clearly indicative of what might be termed an irritable uterus; in individuals liable to frequent miscarriages, and in whom the stomach and bowels suffered much sympathetic disturbance. In these cases there is, we believe, generally a disposition to change of uterine structure; inasmuch that we should say that a patient who has obstinate hysterical symptoms, and now and then a paroxysm, in early life, or between twenty and thirty years of age, has, in a majority of instances, a predisposition to serious uterine disease, requiring great attention. As such patients advance in life, it will be found that the symptoms become more troublesome, and the sympathies of the whole constitution stronger; whilst in many of the cases there takes place a congestion in the vessels of the uterus, or a sub-inflammation, or indolent tumours are formed, or polypi are thrown out from the interior of the uterus, or the uterus descends lower than its natural position, or malignant disease makes its appearance. We should observe, although it seems to contradict the little that is recorded of the morbid anatomy of the disease, that in the most confirmed and striking examples of ovarian disease which we have met with, there have never been any hysterical symptoms, even of the slightest kind.

These observations, which are the simple result of some attention paid to this subject

* Dict. des Sciences Méd. art. *Hystérie*.

† For an illustration of this the reader is referred to the case of a nun in Sauvages' Nosol. Method. tom. iii. We cannot venture to quote the treatment, although recorded in a learned language. The substance of the ancient uterine theory and some of the singular methods of cure which originated in it may be read in Sennertus, tom. iii. lib. iv. pars ii. sect. 3, cap. 4. *De suffocatione uteri*; and a refutation of much of the theory may yet be referred to, with advantage, in the writings of Willis, De Morb. Convuls. and Van Swieten. Willis notices the occasional occurrence of hysteria before puberty, of which we have seen one remarkable example.

during several years, added to the fact that hysteria sometimes occurs before puberty, and sometimes after the cessation of the catamenia,* whilst they confirm the opinion of the frequent connexion of hysteria with uterine disorder, lead us to regard it as having much less connexion with the catamenial function than has been maintained, with a positiveness greater than we think extensive experience would warrant, by some of the most recent writers on hysteria. The question is of great practical importance; but we must now leave the consideration of it to the reader.

We are ourselves convinced, then, that the uterus is not the only organ of which the irritations may so affect the nervous system as to produce hysteria; and this not only from the above considerations, although supported by additional cases in which the uterine functions have continued to be perfectly performed,† but because there is in many instances of hysteria such evident disorder of other functions, and so manifestly, as it has appeared to us, leading to every form of nervous irritation of the hysteric kind up to the paroxysm itself. We might, indeed, adduce the occurrence of hysteria in *men* as at once decisive of the question, but we do not think it absolutely necessary to the argument; although, if such cases are admitted, they must inevitably be taken as putting an end to it.

Among the most frequent causes of hysteria next to uterine irritation, must be placed gastro-intestinal irritation; whether from excess, or from improper food, or from depraved or deficient secretions, or from diminished peristaltic action, and the delay in the intestines of the natural excretions. The extent to which the proper evacuation of the bowels is neglected in female patients is almost incredible, and is so often the sole cause of the ailment under consideration and of many others, that we cannot wonder at the general acceptance of the aloetic or purgative treatment of their disorders. The presence of worms has sometimes excited hysteria;‡ perhaps it may often be an unsuspected cause: we have seen the most violent and repeated attacks of epilepsy, which had recurred for many months, cease after the passing of one large round worm. All the causes of indigestion may become causes of hysteria to those whose constitution of nervous system is predisposed to be acted upon in the specific mode, whatever it be, in which it is affected when the hysteric phenomena are produced. In many cases of hysteria there seems to be a peculiar sensibility of the gastro-intestinal mucous membrane, giving rise to irritability of the stomach and bowels, and thus disordering the

nervous system; and such a state may sometimes be the exciting cause of hysteria, sometimes by its influence only predispose the nervous system to the specific irritation of hysteria on the supervention of any of the other causes. The effect of improper diet, either as regards food or drink, in increasing the nervous susceptibility to all impressions, is probably produced by the intervention of this gastro-intestinal exaltation of sensibility, of which indeed, in such cases, there are many proofs. It seems to be in this manner that luxurious livers and excessive drinkers are always at length punished by an uneasy digestion, and by all the pains of what is commonly called *nervousness*; which last, increasing by degrees, sometimes converts a brave man into a coward, and invariably disqualifies men more and more for great and original undertakings, and even for sustaining the ordinary reverses and agitations incidental to social life. When it is considered that the nervous expansion over the intestinal tunics has been described as analogous to the expansion of nerve constituting the retina, we can readily believe that much disorder may be effected by irritations of this nervous expansion without necessarily ascribing them to circumscribed attacks of enteritis, as M. Broussais has done. In many cases, in which no positive signs of such inflammations exist, the irritations cease or are greatly mitigated on the appearance of fæces indicative of depraved secretions; cases described by the older physicians as abounding in *phlegm*. The motions in such cases are dark or olive-coloured, sometimes passed with much pain, although not hard, and seldom procured without medicine. The excessive flatus which is the torment of certain hysterical patients is in all probability connected with some morbid condition of the intestinal nerves; may in fact be looked upon as an excess of a natural product in the intestines, the result of deranged actions. Partly from the stimulus of so much air, and partly from the morbid condition of the intestines, which produces it, the muscular fibres of the intestines are thrown into commotion, or at least excited to vehement action, creating a feeling of movement and a rumbling noise which becomes a source of annoyance to the patient. Upon this disordered state spasm frequently supervenes, and it would seem generally to commence in the lower part of the intestines, near the termination of the colon in the rectum, and to ascend, producing the feeling of globus already described.*

* Other irritations of the intestines seem also to commence in the lower portion, and to proceed upwards. Diarrhœa commonly precedes vomiting in the cholera. Herniæ excite irritation *above* the protruded portion of bowel or omentum. The symptom of globus has been noticed in some instances of severe gastritis, and is in such cases supposed to depend on spasm of the cardia extending to the œsophagus. Broussais considers it as indicating inflammation of the whole stomach; but what bears somewhat on the present subject is that in these instances the capacity of the organ has been found greatly contracted, reduced to the capacity of the small intestine. See GASTRITIS.

* Willis, op. cit. See also Dr. Bright's Cases, vol. ii. case ccxx. This was a case of nymphomania after cessation, accompanying uterine disease. M. Georget would consider it a case of cerebral disorder.

† For a case of this kind, in which there was hysteria with temporary paralysis and no uterine irregularity, see Parry's Posthumous Works, vol. i. p. 370.

‡ The hysteria *verminosa*. Sauvages, Nosol. Method. tom. iii.

It happens, however, not uncommonly, that even when the state of the uterus is the real cause of the hysteric disorder, the suppression or insufficiency of its accustomed secretions is followed by such derangement of the digestive organs, that the hysteric phenomena appear wholly to depend upon the latter; a fact which did not escape the observation of Whytt, who remarks that "when the menses are obstructed, the stomach generally suffers first, and by means of its *consent* with almost every part of the body, gives rise to many of the complaints which follow. Thus the hysteric convulsions and other violent symptoms which are sometimes occasioned by a sudden stoppage of the menses, do not seem to proceed immediately from the uterus, but commonly from the stomach and bowels, whose nerves are first affected either by their sympathy with those of the womb, or by the blood which should have been discharged by this organ being partly turned upon the alimentary canal."* But, on the other hand, it is equally certain that attention to the order of the phenomena in hysteria will often detect the priority of the intestinal disorder, which the uterine irregularity seems, in such cases, to follow as a consequence. Such are the complications met with in practice; baffling to those who trust wholly to their books, and only to be prepared for by a careful clinical education; a kind of education not confined to the schools, but within the reach of every practitioner who has access to numerous examples of disease.

Either the uterine disorder or the intestinal disorder, which are thus seen to have the power of producing each other, may produce the nervous irritation, or the congestion, or whatever morbid condition it may be, of the nervous system, or of certain portions of it, which induces the hysteric paroxysm. Either of them, also, may thus act as a cause predisposing to the hysteric paroxysm, or as a cause exciting it without the supervention of any other known cause.

Another cause of hysteria, also, sometimes predisposing to, sometimes exciting the paroxysm; sometimes connected with uterine disorder, sometimes leading to it; is a plethoric condition of the body, or of the nervous system, or apparently of portions of that system. The appearance of the patient commonly indicates the presence of this cause in patients who are indolent and overfed; but as it is often combined with an oppressive feeling of debility, with a pale or bloated complexion, and a languid pulse, and as the plethora may exist with reference to the strength of the patient only, it sometimes escapes attention.

Both hysterical and epileptic attacks are occasionally attended with hemoptysis. We think, also, that it is too common to set down cases of periodical vomiting of dark-coloured or sanguineous fluid as dependent on uterine disorder, when, although the menstrual discharge may be rather less than natural, really dependent on plethora. Patients of the de-

scription here meant complain of pain of the stomach, distention, flatus, and coldness of some portion of the abdomen, followed by the vomiting. The pain and other symptoms alternate with severe pain at the upper part of the head, accompanied with several symptoms which may be called nervous, such as a sense of coldness in the eyes, nose, and face generally; and they are subject not only to great agitation of spirits on slight occasions, but to severer symptoms, such as temporary insensibility, seemingly connected with fulness of the cerebral vessels. They also often complain of pains and swellings of the hands and arms, and feet and legs; they are soon and much disordered by errors of diet; inclined to be fat; subject to profuse perspirations on making slight exertions; and their bowels are constipated, as well as the catamenia deficient. In such cases the plethoric condition finds no natural or no effectual relief; and bleeding and medicine must be the substitutes for the dietetic restraint and proper regimen which often cannot be enforced, as well as for the vomiting which has already established itself.

All convulsive affections seem to be capable of being produced both by plethora and the opposite state of debility, or deficiency of nourishment. This may arise from defective powers of digestion and assimilation, or be a consequence of previous disease of some continuance, as leucorrhœa and menorrhagia; or of a recent confinement;* or of protracted nursing; or arise from various other causes which it is unnecessary to enumerate, including any which may lead to a depravation of the blood as well as to deficiency of its actual or relative quantity. It may be worth while to mention that repeated bleedings and excessive purging may have the same effect.†

Some of the older writers laid considerable stress on the influence of a gouty constitution in predisposing to hysteria. Facts of this kind are not easily verified; and hysteria may occur in a gouty family without being really connected with a gouty constitution. There can be no difficulty, in an age when a new and more enlightened pathology of the fluids seems to be dawning, in admitting so much of the ancient humoral pathology as to allow that either a gouty or any other morbid matter in the blood may be the occasional exciting cause of those nervous irritations which characterize a susceptible temperament, just as, in other cases, the same morbid matter, by irritating the nerves of the extremities, appears to excite the common pains of gout and rheumatism. The nervous irritation in these latter examples is sufficiently well established; the existence of a morbid matter yet remains to be proved.

Climate, seasons of the year, occupations, and sex, have generally been enumerated among the causes creative of a predisposition to what has been termed *mobility*, and what we

* Whytt, opus cit. p. 186, who also refers to a case in the Phil. Trans. No. 174.

† Sauvages. Nosol. Method. "a repetitis phlebotomiis et catharticis."

* Opus cit. p. 177.

have spoken of as increased susceptibility of the nervous system. The situation of a country, its soil, its climate, and even its government, determine the occupations of the mass of its inhabitants, and by giving greater or less excitement to their faculties, naturally cause more or less activity and enterprise. The susceptibility which predisposes to various nervous disorders is thus undoubtedly increased or lessened. All the disorders of the mind are said to be less common in Spain and in Turkey than in England. But, as regards hysterical disorders, it is seldom that we have any reason to refer their origin to causes of such general operation; except it be to climate and to seasons of the year. Joseph Frank says that his own observation has taught him that spasmodic affections of all kinds are more frequent in Italy than in any other countries.* Yet the women of Lapland have been described, although we cannot quote our authority for it, as being so susceptible to impressions as to faint on any sudden noise occurring near them. We have ourselves often remarked the increased discomfort of hysterical subjects in warm and showery weather; and especially, without such decided reference to increased temperature, their aversion to the supposed disturbing influence of a cloudy sky: they sometimes say that they "can feel the clouds."

Dr. Mead enumerates hysterical disorders among those which are influenced by the moon; returning when there is a new or full moon; and he refers to a case related by Dr. Pitcairne, and to two recorded by Piso,† one of which was that of "a lady of quality, whose left cheek and part of the neck were wont to swell very sensibly about the new moon."‡ We have already spoken of the modern disregard of all notions of this kind, (see the article DISEASE, vol. i. p. 620,) and shall say nothing more on this occasion than that, true or false, fanciful or real, we have hardly ever known a patient affected with a nervous disorder whose attendants did not stoutly assert these much derided influences.

The influence of sex and of education is more generally admitted, and indeed much more palpably and generally evinced. Medical philosophers declaim, and will long declaim in vain, against a system of education which, apparently solely directed to securing an advantageous establishment to young females, leaves them at once artificial and ignorant; full of the terms of many kinds of knowledge, but wearied or disgusted with all; trained to subdue the feelings only so far as to form alliances from selfish motives, but unprepared to be the companions of intellectual men, or to bear the

neglect which their insipidity, or motives as selfish as their own, too often entail upon them. The predominance of the uterine system, although much less marked in the generality of cases in this country than in those in which the observations of some of the continental writers have been made, is yet sometimes sufficiently declared; and the disappointments of females who begin to feel that they are no longer young, and yet who have not become wives, have in many cases effects sufficiently observable. English practitioners pay, perhaps, too little attention to these circumstances; and, exercising their profession in a country where the passions and emotions have but a limited external manifestation, and where the female character is less intensely expressed, sometimes seem to forget their silent operation on the frame, and are inclined to charge the medical writers of other countries with being somewhat fanciful and extravagant.

"The social position of women," observes M. Georget,* "renders the sex, already subjected to peculiar ills from their organisation, the victims of the most acute and painful moral affections. Their moral existence is entirely opposed to their faculties; they possess a will, and are constantly oppressed by the yoke of prejudices and social arrangements in their infancy and early life; of a husband in their youth; and of indifference in old age. Sensible and loving, they must only love when the master orders them: they are for ever constrained to concentrate within themselves the most powerful passions and the gentlest inclinations; to dissemble their desires; to feign a calmness and indifference when an inward fire devours them, and their whole organization is in tumult; and to sacrifice to a sense of duty, or rather for the happiness of others, the happiness and tranquillity of a whole life." "The education of young women, of which the tendency ought to be to repress the affective faculties, already too prominent, has, as now conducted, opposite effects. A mother would be in despair if her daughter did not give early indications of *acute sensibility*, and nothing is neglected that may endow her with this fatal present: inaction of the muscular system; the cultivation of music; frequent parties, balls, and public entertainments; the understanding unemployed; or books perused which do but excite certain feelings, and nourish illusions contrary to the actual state of society;—such are often the different influences to which girls are subjected at an age when the powers of the mind should have quite a contrary direction. The end answers to the means; one order of faculties alone is exercised; and this will become predominant over the reasoning faculties, and the cause of a host of vaporous, hysterical, hypochondriacal, and maniacal disorders."

Making due allowance for the different character and habits of the two countries, we cannot doubt the justness of these censures. And even in England, where an acute sensibility is

* Quamvis spasmi nec in regionibus septentrionalibus desiderantur, eos tamen longe frequentius in Italia obvenire, mea docent observationses. Prax. Med. Univ. Præc.

† De morbis a serosa colluvie. Piso attributed hysteria to a serous colluvies at the origin of the nerves.

‡ Mead, On the influence of the Sun and Moon upon Human Bodies, and the Diseases thereby produced.

* Op. cit. vol. i. p. 193.

less desired for young women than accurate powers of *calculation*, the improper expectations, the vain rivalries, the restless and frivolous pleasures of fashionable life, are but too well calculated to produce all varieties of nervous disorders in young persons whom an affected refinement has debarred from active and natural exercises, and whose minds have never been accustomed to the exercise of self-control.* In the middle classes different causes are in operation; and women of that class are at present subject to mortifications arising from the inferiority of their husbands in attainments and in cultivated sensibility to themselves. The gentle passions and the romantic feelings, utterly banished from the cold atmosphere of the higher ranks, have yet some sway in a class below them, and there produce occasionally their peculiar effects on the female frame.

But there are causes of disquietude which pervade every rank; for if the utmost attention to fashion could wholly still the voice of the natural feelings, it cannot suspend the inevitable flight of years and advance of old age; a phantom uninviting in its aspect to all, but to the fair, the frivolous, and the vain, a spectre of the utmost horror. On this subject M. Georget has expressed himself in language too applicable to every nation. "Man, as he advances in age, increases in power, in fortune, in dignities, in consideration. It is quite otherwise with woman: the progressive steps of life, when youth has once passed away, are for her an actual descent in the social ranks, and the sources of painful moral affections. There are few who can see without regret their attractions fading, and the flight of smiles and love, and the loss of the empire of beauty: these losses are felt the more keenly, because it is from others that the first knowledge of them is derived; for self-love makes many struggles, and the unwelcome persuasion is only established after many mortifications." "If devotion does not effect a salutary diversion in the ideas, or if a truly philosophical resolution does not early impart to woman the courage and firmness necessary for clearing this terrible abyss, the critical age becomes a stormy period, abounding in vapours, mental disorders, hysterical and hypochondriacal affections, often ascribed, without consideration of their origin, solely to that period of life, or to the cessation of the catamenia."

The causes acting through the mind which have now been mentioned, are occasionally exciting causes, but much more frequently only predisposing. Mental impressions of a more sudden and transient character may act as causes immediately exciting a paroxysm; such as anger, grief, terror, or great surprise. It is unnecessary to accumulate illustrations of the powerful effect of these impressions; the slightest operation of them in their lower degrees

is familiar to the commonest observation. But from this slight operation, involving mere disorder in the vascular and nervous systems, indicated by blushing or paleness, by palpitation, by increased excretions, by hesitating speech, may be observed gradations to the more severe results of slowly formed disease of structure, as in the heart; or of changes more rapidly produced, though less important, as in the colour of the hair. More commonly, however, the severer results are produced by causes long operating on the mind: whilst the more sudden impressions, when their violence is greater than ordinary, produce a simple loss of power in the nervous and muscular systems; the state of syncope, from which there is a gradual recovery by a moderate reaction: but this loss of power may be greatly protracted, no reaction may take place, and death may ensue; or overwhelming reaction may be produced, and fatal apoplexy. Generally, however, the severer shocks lead to a reaction, which is violent without being fatal; and after the feeling of faintness or depression, or sometimes almost without time being afforded for that feeling, the muscles are thrown into disordered and energetic motions, and all the vascular and nervous actions become irregular or tumultuous, and assume the form of hysteria or of epilepsy. Even the mimic representation of the more agitating passions will sometimes produce these effects; and hysteria has converted the cries and screams of the actress into reality, whilst the female part of the spectators have been similarly affected. Dr. Gregory used to relate, that when Mrs. Siddons first appeared in Edinburgh, these effects upon the audience were so common, that it became quite the fashion for the young men of the place to attend the theatre to carry off those affected; a service which was termed "carrying off the dead."

We cannot help again, in this place, endeavouring to impress upon the reader that sometimes the reaction after these sudden impressions takes the form of acute delirium. There is no inflammation of the brain or its membranes, no discoverable change to be detected after death, when death occurs; and the best treatment is *not* the active treatment sometimes resorted to, but the treatment proper for hysteria. Above all things, the practitioner must avoid sending such cases to a madhouse. Whenever such attacks are found to have suddenly supervened on an acute moral impression; after violent disappointments of the affections; vehement invasions of jealousy; or even after marriage, when there is reason to suspect the existence of peculiar physical circumstances which can here only be alluded to, the practitioner cannot be too little precipitate in his measures. One or two remarkable cases of the latter kind have come to our knowledge, where the result was fatal; and we think their real nature has not been sufficiently reflected upon.

Another mental influence productive of hysteria requires to be mentioned, because it suggests certain precautions in the management of such cases; namely, the influence of imita-

* The reader may be advantageously referred to Dr. Parry's admirable remarks on the Effects of Habits in creating Predisposition to Disease. *Elem. of Pathol. and Therap.* vol. ii. See also the article PHYSICAL EDUCATION.

tion. One hysterical patient in the ward of an hospital will sometimes produce many more. Of this an instance has already been mentioned on the authority of Dr. Bright; and these effects have been so often noticed, that, generally speaking, no place can be less suitable to patients affected with hysteria than an hospital. Even in private practice such communications of disease occasionally take place. Dr. Gregory used to mention an amusing instance of a lady's maid thus involuntarily imitating her mistress; and M. Loyer Villermay mentions similar accidents in the article *Hystérie*, in the *Dictionnaire des Sciences Médicales*. Dr. Darwin speaks of the inmates of a nunnery who were all afflicted, one after the other, and at length altogether, with a desire to imitate the inharmonious nocturnal sounds of cats. Dr. Whytt alludes to a disease common in the island of Zetland, and almost exclusively affecting young unmarried women; sometimes, however, appearing in the male sex; in which there was first violent palpitation, and then the patients fell to the ground; their arms and legs being either convulsed or rigidly extended, and their respiration difficult. The great inconvenience of this affection was, that when any one was attacked with it, at church, in the market, or in a public place, straightway all who had ever been subject to it were attacked again; whilst others, in the great disturbance thus occasioned, became for the first time similarly affected. All these examples merely illustrate the proneness to imitation which is observable in all persons in early life, and which continues longest to adhere to the character of nervous and very susceptible persons, and, consequently, to many women. This is particularly seen in schools, which have sometimes furnished remarkable cases of squinting, stammering, and awkward motions, solely occasioned by imitation.

The celebrated Boerhaave, his nephew Kaau Boerhaave informs us, was consulted concerning the occurrence of a more serious affection which was introduced into the house of charity at Haerlem. A girl having become subject to paroxysms of a convulsive disorder, in consequence of fright, one of the bystanders on the occasion of one of her attacks had become affected in the same way, and then a third, and afterwards a fourth; and subsequently almost all the boys and girls in the institution. Like the people of Zetland, too, as soon as one fell into a fit, all the rest followed. The malady was considered to be epileptic, and all the usual means of relief were tried without the least effect. Boerhaave, therefore, determined on trying what could be done by a powerful mental impression; and, with the concurrence of the magistrates, caused several portable furnaces to be introduced into the house, containing burning coals; and in these furnaces were placed irons bent to a peculiar form, for the purpose of being made red hot. Assuming great gravity and dignity of manner, he declared, in the hearing of all the boys and girls, that other means being useless, it was requisite that whoever became attacked with

the fits should immediately be burnt in the arm with one of the bent irons, and to the very bone. It is added that the children, terrified by the idea of this remedy, were enabled to resist all tendency to a recurrence of the troublesome disorder which had affected so many of them.

Dr. Haygarth was consulted, in 1796, respecting a convulsive malady which prevailed in the island of Anglesey, and chiefly affected females. The symptoms were, a pain in the head or side, succeeded by violent twitchings or convulsions, during which the shoulders were nearly brought together. This disorder excited great alarm, and in the course of two or three months eighteen girls had become affected by it. Other instances are related in a pamphlet of Dr. Haygarth's;* and we shall not dwell longer on this part of the subject.

Before concluding our notice of the causes, we would observe, with respect to the cases of *hysteric asthma*, that, when the frequent connection between indigestion and asthma is considered, it will easily be supposed that the exciting cause of this particular form is often a disordered state of the stomach and bowels. But this complication is by no means invariable in hysteria; in which the asthma is often dependent on simple nervous irritation, produced by various causes; a fact which may be readily admitted when we recollect some of the nervous symptoms even of common asthma; the irritability preceding the attack, the urina profusa, the periodicity of the paroxysms. The nervous irritation may be of various origin: sometimes, doubtless, in the intestinal canal; often in the uterine system, particularly in the hysterical; and sometimes in impressions on the mind; the irritation being transmitted along the respiratory nerves with a facility which we only attempt to explain by referring to other instances of their prompt sympathies equally inexplicable.

The same observation may be extended to hysteric palpitation of the heart. No symptom more frequently arises from a disordered stomach than palpitation, and such may be its origin in some cases of hysteria. But the same system is a most familiar consequence of mental impressions, and of various other irritations; in all of which cases it is referred to the law of nervous sympathy. Few impressions capable of inducing nervous phenomena fail to produce palpitation; and sometimes it may be found that the paroxysm *consists* of palpitation; which perhaps takes a periodical form, with just so much of other hysterical symptoms as to create a suspicion of its real nature.

The headach, also, so commonly afflicting the hysterical, is known to be the commonest of all attendants on indigestion: it is also particularly common in females at the monthly periods. But it will undoubtedly often be found to occur in the hysterical as a direct con-

* On the Imagination as a Cause and as a Cure of Disorders of the Body; exemplified by Fictitious Tractors and Epidemical Convulsions. 1800. See also Rees's Cyclopædia, article *Imitation*.

sequence of nervous irritation; neither yielding to the remedies of indigestion, nor affected by the periodical functions of the uterus, nor relieved by repeated detractions of blood; indeed, sometimes much aggravated by the latter; but greatly mitigated, and sometimes banished very speedily and entirely, by what are called nervous medicines. We dwell on these apparent minutiae because they are really of importance in practice; and because great attention to the real causes of the hysterical phenomena will often save much time and spare the patient from the infliction of much unnecessary medicine.

There are circumstances connected with the hysterical headach, well known to all observers, but not easy to be explained. One is, the very common limitation of the pain to a small space above the eye. Sydenham was content to ascribe it to an "irregular motion of the spirits, in which all the spirits are collected in a certain point of the pericranium." It is easier to see the futility of this explanation than to furnish a better. Sydenham seems to have been much pleased with the solution, for he adds,— "and this contraction of all the spirits into a kind of point, differs little from the collection of the rays of the sun by a burning glass; for as these burn by their united force, so those for the same reason cause a pain, by tearing the membranes with united violence."* The difficulty of giving a proper explanation of this peculiar pain is, however, not greater than that of accounting for the pain under the left breast in the tedious cases already described; and the pathologist is sometimes able to do no more than thus to escape one difficulty by pointing out another which is analogous to it. The intermissions and returns of the pain belong, in like manner, to many affections dependent on morbid conditions of the nervous system; and although, like them, sometimes occasioned by obvious recurring causes, are also sometimes as little understood as the paroxysms and intervals of neuralgia, of epilepsy, or of insanity.

Pathology of hysteria.—Nearly all that can be properly said to have been ascertained respecting the pathology of hysteria has been incidentally spoken of in the foregoing description of the varieties of the disorder and of their various causes. The malady chiefly affects women, or men of a peculiar temperament, or whose constitutions have become enfeebled by intemperance, or by excessive study, or other causes capable of debilitating the nervous system, and of rendering its power of enduring impressions less than in the natural state. A nervous system thus susceptible by original constitution, or thus enfeebled, feels impressions more keenly, and responds to them more forcibly than is seen in firmer organizations, or in a state of perfect health, and, thus prepared, may be excited to disordered actions by numerous accidental causes. In the female system the exciting cause is very often an irritable or morbid condition of the uterine system. But, as this

state of the uterine system appears to transmit an irritation from the uterine nerves to the nervous centre, which irritation is reflected from the centre to the nerves of other parts of the system; so similar irritations appear to arise, in other instances, from other extremities of the nervous system, and especially from the intestinal. In other cases, again, the nervous centres are more immediately irritated or disturbed. The reflected irritation, or that transmitted from the nervous centres, seems most readily to be conveyed to the nerves which preside over the motions of the intestines, and of the heart, and to those of respiration; parts and functions almost always the first seat of the hysterical phenomena. But the irritation may be more diffused; may affect the organs of locomotion and of sensation; and, partly from the specific irritation of the disorder, partly from the manner in which the circulation is affected, (for it is difficult in such a general disturbance to assign a specific cause to each separate phenomenon,) there is a complete loss of the power of moving, and a loss of sensibility and consciousness. It is very probable that the primary irritation of the nerves is soon attended with some alteration in the manner in which the circulation of blood is carried on in them; and the nervous centres may be similarly acted upon. As the disease is seldom fatal, the appearances which have been found after death have for the most part been the mere effects of long-continued disorder of organs from whence the primary irritations have arisen, as of the uterus and its appendages; but in other cases, in which death has supervened in the form of apoplexy upon the hysterical paroxysm, the disordered circulation in portions of the nervous system has been sufficiently manifest in the apoplectic appearances. A state of fulness, of congestion, or of sub-inflammation, in portions of the spinal marrow, may probably often exist. There is, however, every reason to believe that conditions of the nervous system, inconsistent with the proper performance of its functions, often exist without any palpable change in the quantity of blood circulating in the portions of it which are morbidly affected; and that in such cases the functional disorder may leave no visible trace of any kind. On the other hand, sudden and violent changes in the state of the circulation very commonly affect the functions of some part of the nervous system; and even gradual changes in the mere quantity of the blood induce or predispose to all the irritations of hysteria.

If we endeavour to be more precise as regards the exact nature and place of the nervous lesion, we can only be assisted by recollecting the symptoms of an irritated, injected, inflamed, or disorganized brain; and also that the spinal chord may be in like manner affected in any part of its length. It has been observed by pathologists, that when the upper portion of the chord is affected by disease, trismus, impairment of articulation and deglutition, and oppression of the breathing, are pro-

* Op. cit. p. 379.

duced; and that even palsy and death from asphyxia may ensue. When the cervical position has been diseased, tetanic rigidity or convulsions of the muscles of the neck, or palsy of the muscles of the trunk, and paralytic weakness of the diaphragm have been noticed; and results little different have been found in examples of lesion of the dorsal portion.* In cases in which the lumbar portion of the chord is diseased, the lower extremities are almost always paralysed; and first, there is retention, and eventually incontinence of urine and of the faces. These facts, which may, perhaps, be considered as established, point in some degree towards the probable locality, though not very decidedly to the nature, of the irritation in some of the forms of hysteria.

That in all the cases, then, of hysterical disorder, there is a disordered state of some part or the whole of the nervous system, seems to be proved by all the phenomena, as well as by the causes which excite their appearance; but we see no reason to believe that there is always a state of vascular fulness, congestion, sub-inflammation, or any analogous condition of the bloodvessels. And, although the disorder of the nervous system may be, and very frequently is, induced by evident uterine irritation, it no less evidently arises, in other examples, from causes productive of irritation in other parts of the body, and also from causes acting directly upon the mind. If, however, we cannot concede to M. Villermay, that the ancient and revived doctrine of the invariable uterine origin of hysteria is true; neither can we agree with M. Georget to consider it, as Willis had done before, a simple disease of the brain; nor with Mr. Tate, that it is always produced by a morbid state of the spinal marrow, connected with the irregular performance of the functions of the womb.

The existence of an original susceptibility in excess in the nervous system of hysterical patients, is an assumption warranted, we conceive, by all observation. The natural or congenital constitution of the nervous system, and even of different portions of it, is most plainly discerned to be different in different individuals. From the very cradle may be observed a different degree of sensibility to impressions; and even a different countenance, impressed by the hand of nature herself, before human feelings have written their deeper lines upon it; a countenance indicative of a distinct and individual character, which is associated with an individual mode of receiving and being affected by external circumstances, and of exercising the internal faculties upon the impressions received. As the individual being grows up, the results of the original organization, modified but not changed by education and various accidents, are observed in all the varieties between stupid insensibility on the one hand, and morbid or too ready excitement and activity on the other. The excitement and the activity are in dif-

ferent individuals more conspicuously manifested in different parts of the mixed system of body and mind. Thus, some are seen to be endowed with almost inexhaustible muscular energies, and some with vast powers of intellectual perception and combination; whilst in some the functions of the mind are feeble or disturbed, and in others divers other functions are debilitated or disordered. In the hysterical patient we may observe the most intense development of susceptibility, connected with a singular proneness to irregular actions, often arising from slight causes; the natural proportion designed to exist between the impressions of the external world and the sentient human system being in them not preserved.

The various impressions which thus become the causes of hysteria, (to confine our attention to this form of their effects,) if always supposed to act by nervous excitation, yet sometimes so readily and so early excite the circulation, and without the visible antecedence of any nervous change, that the phenomena seem to be referable to the vascular disturbance. The greater susceptibility of the nervous, or greater irritability of the vascular system, in different constitutions, exercises considerable influence. It would seem as if a mental impression, or a disordered state of the stomach, or the presence of worms, flatulency, or acidity in the intestines, or a disturbed uterus, may in one case produce a direct nervous excitement, and in another act first on the heart and arteries, and, through disorder in them excited, lead to irritations in the brain and nervous system; and, lastly, through the irritation of the brain and nervous system, to disorder in several functions, different in different individuals; the respiratory organs being most affected in one, the intestines in another, the kidneys in a third, and the brain (still a secondary effect) in a fourth. The ultimate results are various; sobbing, or crying, or laughing in one case; in another, the hard and barking cough; in one, distention of the stomach and bowels, and globus; in another, diarrhoea or obstinate constipation; in one, copious urine, in another suppression; in one, confusion of mind, in another excessive caprice and love of change.

The links of such a disorder are too numerous to leave room for the affectation of laying down precise pathological rules as the measure of each case. Even another link must in some of the cases be added; for in the case of disordered stomach or bowels, for example, being the cause of the primary irritation which ends in the production of hysteria, that irritation itself, primary as it is with respect to the hysteria, is but secondary to some antecedent failure in the just performance of the vascular or nervous functions, or both, of the part in which such irritation first arises; and this failure itself may be occasioned by too great or too scanty a supply of blood, or too great or a deficient supply of nervous energy, or some other irregularity in the functions of one or both of

* *Craigie*. Elements of General Anatomy and Pathology, 1st edition, p. 429.

these systems, as relates to the constitution of the part the functions of which are first seen to be impaired. Yet it is upon a just consideration of some of these first links of a long chain that our best hope of a radical cure must in a great measure or wholly depend.

The object or final cause of all the diversified hysteric movements seems to be the equalization of the circulation of the blood, and the removal of an irritation of which the nervous system is conscious. We can recall no instance from our observation of convulsions excited without some intention, more or less obvious, to be effected in the general struggle. They commonly indicate the dominion of the irritated or pained brain, and are instinctive efforts for its relief; of which hysterical patients in particular sometimes express their own conviction.* It is justly remarked by the intelligent observer quoted below, that the muscles called into action in hysteria are chiefly those employed in *great exertions*.

Treatment.—We believe there are few disorders of which the practitioner generally undertakes the management with less willingness than hysteria. Its causes are so often obscure, or slight, and not to be wholly avoided, and its phenomena are so changeable and baffling under all kinds of treatment, that it is often left to itself, as a constitutional affection over which medicine has no power. Certainly very little benefit is to be expected from a bold and indiscriminate practice, and no immediate or striking results are to be looked for under the best considered plan of treatment; but those who take sufficient pains to ascertain the origin and complications of each case, and have perseverance enough to pursue a plan of treatment adapted to a chronic affection, and often requiring the whole health of the body and mind to be modified, will find that there are many cases, very unpromising at first sight, which may by such means be greatly relieved or wholly cured.

Cases, assuredly, occasionally present themselves, so strange in their character, and so extensive in their complications, that the practitioner who has not been led to refer their almost innumerable symptoms to some general principle may imagine that they are only created to bewilder him and to discredit his art; and be to the last degree perplexed what plan of treatment to adopt, or with what measures to begin. Referring to the notes of a single case, not long ago seen by us, we find, contemporaneously existing, or at least complained of in a continuous catalogue detailed to the ear of the practitioner by a married female, of about thirty years of age,—head-ach; pain of ears and occasional deafness; frequent loss of voice; tightness of chest; dry, loud, sonorous, and very peculiar cough;

dyspnœa; spasm about the throat, with blackness of the face supervening; pain of arms; palpitation; acute pain of the epigastrium, and sometimes in the left lumbar region; irregular appetite for food, and chiefly at night; costive bowels; very scanty and high-coloured urine, with copious whitish sediment, but sometimes abundant, and pale as water; menstruation quite suppressed, after being long defective; much pain of the lower part of the back; pain of the legs; disturbed sleep; great coldness and insensibility of the surface, particularly in the lower extremities, whilst heat applied to them produces mental excitement and a disposition to loud singing; the palpitations induced by exertion, as well as difficult breathing, cough, much agitation, and violent crying. Of such a case, a kind of epitome of all hysteric sufferings, the first view would seem to be most confused, and the first opinion most unfavourable. If the practitioner institutes a diligent search after local symptoms, he finds no satisfactory end to his search; and if he undertakes to prescribe for every symptom, as indicative of some local affection, he exhausts the art of prescription without success; new symptoms arise when old ones yield, and he at length gives up the contest in despair.

To attain clear views of the proper arrangement of these and all other gradations of the malady, it seems best, therefore, to speak of the treatment,—1. with reference to the paroxysm; 2. when hysteria depends on causes of a general nature, as plethora, or the opposite condition of various approaches to anæmia, debility, &c.; 3. when connected with uterine irritation; 4. with gastro-intestinal disorder; 5. of the treatment of some particular symptoms; and, 6. of the preventive treatment in general: we shall thus be enabled, without unnecessary subdivisions, and without neglecting complications which no arrangement can simplify, to comprehend every practical consideration of importance.

Treatment in the paroxysm.—During a fit of hysteria, the objects of all that can be done by the assistants are, to guard the patient from avoidable injury, and to shorten the duration of the fit itself. The importance of both these objects depends, of course, a good deal upon the form of the paroxysm. When there are violent muscular agitations, the patient may be seriously injured without the care of those about her; and when much pain attends the fit, or when there is deep coma or intense spasm, our anxiety must be greater to put an end to the attack.

All the details of the methods of restraint to be employed by the assistants may be resolved, whatever appearances of complexity may be given to them, into guarding the patient from injuring herself by her hands, by her teeth, or by striking the head and upper part of the body against any hard substances; and when these objects are gained, further restraint is useless, and perhaps hurtful; for the harmless although irregular actions which remain are to be considered as

* Ce sont les malades elles-mêmes qui donnent cette explication, comparant ce qui arrive dans cette circonstance à l'espèce de roideur générale que l'on oppose machinalement à toute sensation douloureuse, vive, et instantanée."—Georget.

many natural means of relief. The best way of guarding the patient from any injury from the teeth, is to put a napkin, several times folded, between them. According, however, to the degree of consciousness possessed by the patient, should the attendants endeavour, by firmness, calmness, and well-timed exhortations, to cause the person affected to exert her own power of self-controul. For this purpose the operation of fear has sometimes been resorted to; and the success which has attended it shews that the patient is capable of being roused to exertion: but if sometimes successful, it is not always safe; violent convulsions have in some instances been occasioned by it, converting a quiet form of the disorder into one of an alarming aspect.

If the symptoms indicate a forcible determination of blood to the head, no attentions in the fit will more successfully mitigate the occasional convulsive actions than such as are directed to moderating such determination. The head may be raised, and towels wrung out of cold water applied to the forehead; warmth being at the time applied to the feet. All tight clothing about the neck or chest should be loosened. In the cases going on to complete coma, even venesection may be advisable. When there is less plethora of the vessels of the head, and the fit is obstinate, the patient being at intervals able to swallow, moderate quantities of stimulants are useful; as from half a drachm to a drachm of the spiritus ammoniæ aromaticus or fœtidus, or of the spiritus ætheris aromaticus or sulphurici compositus or nitrici, given in water, medicines which are more suitable than wine or brandy, because less permanent in their effects, and yet efficacious. Advantage may be obtained in slighter cases by sprinkling the face and chest with cold water, as recommended in the article HYDROCEPHALUS for the relief of convulsions; and an abatement of the symptoms is often procured by applying stimulating scents to the nostrils, as common smelling salts: formerly, the smoke of assafœtida or of burnt feathers used to be much employed; and we have witnessed singular effects in some cases of slight convulsion from smelling common mint. More troublesome spasmodic paroxysms, frequently occurring in the fit, may render the addition of the tinctura opii, in doses of twenty or thirty drops, desirable. When the spasms are very severe, and especially when they assume the tonic form, there is commonly a degree of rigidity about the jaws which renders it difficult to administer medicine of any kind. In such circumstances the best effects are produced by enemata, particularly of assafœtida, of which one or two drachms may be so given; an ounce of the oleum terebinthina rectificatum is, perhaps, still more efficacious; we have seen complete resolution of rigid and apparently intractable spasm ensue in a few seconds after its administration in the enema domesticum: it is not necessary that the quantity of decoctum avenæ, which is the best vehicle, should be so great as when the object is to empty the colon; about ℥viii. being suf-

ficient. An enema of vinegar and water, or a mixture of these given by the mouth, are recommended by Riverius* for the suspension of the fit.

Little more can be done in the paroxysm. To keep off a paroxysm is always important; and it is sometimes accomplished by the prompt administration of ℥℥ of the pulvis ipecacuanhæ, which we have also seen repeatedly successful in suspending the morbid actions of the paroxysm, especially in the croupal form described a few pages back. Extremes of heat or of cold have been remarked to bring on the paroxysms,† and should consequently be avoided as much as may be practicable. No effort should be left unmade to induce the patient to exert herself in opposition to the paroxysm; to resist it, as much as possible, by her will, and to feel pride in overcoming it. When any premonitory symptoms are perceived, cold water should immediately be applied to the head; and some of the stimulants already mentioned may be found prophylactic. Other parts of the preventive treatment will be mentioned afterward.

Treatment when dependent on plethora.—Cases of hysteria dependent on plethora may be complicated with defect in the uterine functions, with the suppression of some habitual discharge, or the retrocession of eruptions; and their relief is then to be principally expected from the re-establishment of the defective secretion, the restoration of a discharge to which the constitution has become too much habituated to endure its sudden cessation without derangement, or the solicitation to the skin of the eruption that has prematurely receded. Much more commonly, however, the plethoric condition of those subject to hysteric fits arises from neglect of exercise and from improper diet, and is best relieved by the general treatment of plethora, on which it is unnecessary here to expatiate. We have seen very good effects from one full bleeding; but the frequent repetition of venesection will not be well borne, and may even increase the susceptibility of the nervous system, and cause the continuance of the hysterical disorder in connection with the debility thus induced. The comatose or apoplectic form of hysteria will generally be found connected with too great fulness of the cerebral vessels, demanding careful attention, for such cases have proved fatal. Any immediate danger may be averted by taking away ten or twelve ounces of blood from the arm, or, what generally gives more relief, by cupping behind the neck, or rather between the shoulders, for the practitioners must not disregard the indelible marks of the scarificators. The remaining disposition to cerebral plethora will be easily kept in check by applying a few leeches behind the ears once a fortnight, or every three or four weeks, and by causing the patient to take twice a week, in the morning, gr. ii of the submuriæ hydrargyri with ℥i or ℥℥, or more, of the pulvis

* Praxis Medica.

† Georget.

jalapæ compositus of the Edinburgh pharmacopœia, or a draught of infusum sennæ with two or three drachms of sulphas magnesiæ, and a drachm of the tinctura jalapæ. She should be directed to rise early, to take a tepid or cold shower-bath twice or thrice a week on getting up in the morning, or at night on going to bed: the diet should be moderate, and not consist of much fluid food, as broths, coffee, cocoa, tea, &c. Animal food should only be taken once a day. The patient should not indulge in late hours, nor lie on too soft a bed, nor in a close or confined apartment. Female servants have been rendered liable to hysteria in consequence of sleeping in rooms having no chimney; a fact which it may be useful to notice incidentally, although not directly connected with the subject of plethora. Walking exercise should be most strictly enjoined; the neglect of it is one of the chief causes of the general ill-health of women; they commonly neglect exercise for many days, then take it to excess; suffer from the excess and refrain from walking for many days more; and these ill-judged alternations it is very difficult to persuade them to abandon. The lamentable effects of the neglect of exercise have been pointed out in the article PHYSICAL EDUCATION: we believe that more attention is now paid to exercises and recreation in schools for young ladies than used to be the case a few years ago; and that the voluntary indolence of those who are not at school is much more general, and attended with the worst effects. The exercise taken by the patient will, of course, be various, according to her rank or situation in life: fortunately the best kind of exercise is the cheapest; and of all modes of exercise riding in a carriage is the worst, tending much more to induce than to avert a determination of blood to the head. As respects horse exercise we fully concur with Dr. Parry, who says, "with regard to riding on horseback, it is usually a mere apology for the want of that exercise which Providence evidently intended that man should take by means of his own limbs, and not those another of animal. Accordingly we find, that exclusively of the positive diseases which spring from this mode of gestation when violent, those who trust to its more moderate use, and more especially those who substitute it for accustomed bodily labour, are at least as subject to dyspepsia, gout, dropsy, hemorrhage, the whole train of nervous affections, mania, hysteria, epilepsy, paralysis and apoplexy, as those who lead the most indolent lives."* The same experienced and enlightened physician reprobated in strong terms the mental weakness which was opposed to all voluntary exertions, and which in itself, as proceeding from the neglect of proper exercise, furnished a powerful argument against it. He admirably points out the evils of very warm rooms; of late hours, which always imply so much time taken from the day, and from the animating but little heeded effects of light; and all those indulgencies for which climate or fashion furnish so many apo-

logies. And he notices the instructive fact that various animals dependent on man, and treated with similar indulgence, incur similar penalties. "Thus singing-birds and lap-dogs, which are confined and highly fed, are subject to the whole train of nervous affections; as palpitation of the heart, breathlessness on slight motion, hysteria, convulsions, epilepsy, hemiplegia, and apoplexy."

When, by inducing better habits in these respects, and taking the immediate measures already pointed out, the plethoric condition is so far reduced as to obviate the occurrence of any inconvenience from the use of antispasmodic medicines, these may be variously employed, in combination with counter-irritation along the spine, and other measures which we shall have to mention after considering the next class of cases.

Treatment of cases dependent on various degrees of debility.—Our classification must not exclude from our reader's mind those cases, not of unfrequent occurrence, in which the state of debility is combined with the state of plethora, and which require a judicious combination of several parts of the plan above laid down with that now to be mentioned.

When the general nervous susceptibility, and consequent hysteria on the supervention of slight occasional causes, are not connected with plethora or with vascular excitement of a general kind, venesection, low diet, and saline purgatives, or such as produce watery discharges from the bowels, may exceedingly increase the tendency to the disorder. Local vascular excitement in the brain, for example, or in some portion of it, or of the spinal chord, may require and be benefited by local depletion, and be relieved by external irritations, by means of blisters or the tartar-emetic ointment; but the general measures must be of a different kind. Medicines which increase the patient's strength will here be found to diminish the susceptibility of the nervous system to impressions; but they require to be given with peculiar cautions, for patients of the kind now alluded to generally profess an inability to take any tonic medicine without incurring headach, feverishness, and uncomfortable excitement. Their objections to all medicines in which they detect a bitter taste are commonly insurmountable; and the practitioner is precluded from the employment of the cinchona, cascarilla, calumba, and gentian, although some of these might really be serviceable. In such cases the best resource is found in the diluted sulphuric acid, of which seven or ten drops given in the infusum rosæ compositum, with a drachm of the compound tinctura cardamomi, will be found to form a grateful medicine, which the patient may take twice or thrice in the four-and-twenty hours with great advantage: the addition of *mxv* or *xx* of the tinctura hyoscyami will usefully allay any excess of nervous irritation. If the patient is found, as frequently happens, to make objections to chalybeate tonics, the objections will commonly be avoided by giving these most useful medicines in very small doses, without any sacrifice of their good effects. If the di-

* Op. cit. vol. ii. par. 31, 32.

luted sulphuric acid is given in distilled water, half a grain or a grain of the sulphate of iron may be given in the draught: even a quarter of a grain, or less, given in this manner, is productive of good effects: if more is deemed necessary, gr. ii. may be given in a pill with the extractum anthemidis, or the extract of gentian, night and morning. If the *tinctura ferri muriatis* can be taken without inconvenience, it may be given in doses of from seven to ten drops twice a day. We have generally found these forms of medicine less objected to by patients than the *mistura ferri composita*, although the compound iron pill is taken without complaint, and in doses of eight or ten grains twice a day is a valuable tonic. Of the *vinum ferri* we have little experience; but this or the *mistura ferri* may be given so as to avoid any real or supposed inconvenience to the patient, in combination with the decoctum aloes compositum; a combination which may be especially useful when it is desired to promote the activity of the bowels, or to excite the periodical functions of the uterus. The most delicate females can generally take the sulphate of zinc or the oxyde, in doses of a grain twice a day in the form of pill, with some bitter extract, without difficulty; and we are much disposed to think that the general effect of the mineral tonics will be most satisfactorily perceived when they are given in these moderate doses. We give this opinion as the result of our own observation; but it is only reasonable to suppose that more advantage is gained by attempting the gradual invigoration of the functions, than by suddenly calling on the organs for actions of which the vehemence is disproportioned to their power. Whytt mentions a case in which two hundred and thirty grains of the filings of iron were given daily, divided into three doses, for some months together, in a case of indigestion. The carbonate of iron has also been lately given, as is well known, in enormous quantities; but this kind of treatment does not appear to us to be at all suitable to cases of hysteria. It does not seem that the natural mineral waters of Bath, which formerly enjoyed much reputation in nervous disorders, have of late years been much resorted to by nervous, or at least by hysterical patients; a fact of which we are assured by an obliging communication from Dr. Barlow, but which we have learnt with some surprise. If due care was taken to recommend their use in cases where the hysterical affection was connected with a debilitated constitution, we cannot doubt that it would be attended with great advantage. But the real merits of mineral waters are often lost in a meretricious flame: whilst fashion dictates their employment, they are used indiscriminately; and when the fickleness of fashion leaves them unpatronised, their good effects are no longer thought of.

The warm, sulphureous waters of Cauterets and Bagnales (Bagnoles) are mentioned by Sauvages as being useful in the *hysterica chlorotica*. About four pints are directed to be drunk daily for three days, and a bath is to be taken on the fourth; and the use of the waters

and the bathing are to be thus continued for a month. Those of Seltzer, Spa, Vichy, Barèges, Pyrmont, and Carlsbad, have been recommended.

Sydenham had great confidence in the effects of a milk diet in cases of great debility. He also thought highly of the infusion of various bitters in canary wine, and says that he sometimes advised hysterical women to drink a large draught of canary by itself at bedtime for some nights in succession, and that they were eminently relieved by it, "the whole body having been much strengthened, and such as were before cachectic becoming fresh-coloured and brisk thereby." He also very strongly recommends horse exercise.

To the ammoniatum cupri and nitras argenti, which have sometimes been given on account of their possessing not only a tonic property, but a specific power of allaying nervous irritability, we have never had recourse in hysteria. With the intention of improving the general health, we should especially recommend either the tepid shower-bath of sea-water or of salt and water every other morning; or the sponging of the greater part of the whole of the surface of the body with salt and water every morning. The warm sea-bath may be useful, or, if the patient can bear it, bathing in the open sea.

Change of climate, even within our own island, may become an object of consideration, by way of avoiding extremes of heat or cold. No medical practitioner of observation is now sceptical concerning the effects of changes of weather as well as of climate. We would ourselves generally undertake to predicate, from the actual state of the weather, the situation in which we should find patients of known susceptibility to impressions, or nervousness; and have often noticed their especial discomfort in warm and showery seasons, their continued indisposition in low, sheltered, warm residences, and their as certain relief when removed to a hilly locality. Some of these effects are perhaps accounted for by the variable weight of the atmosphere in various seasons, its lightness always seeming to produce oppression by permitting the expansion of the circulating fluids, except in particular constitutions, to whom such expansion seems to be suitable; other effects may be the mere result of temperature on the nervous substance; and some we should be inclined to ascribe to electrical variations which have not yet received adequate attention.

The refreshing air of Malvern, of the heights of Clifton, or that of the northern parts of the island, may be useful in the warmer seasons. Of that of Malvern we can speak confidently, as regards its surprising effects on pale languid females, whose appearance and health begin to improve almost as soon as they remove thither; it has this great advantage, also, that it may be enjoyed without exposure to the dissipations which seem to form an essential part of a fashionable watering-place. It is mortifying to observe how frequently weak and nervous patients, relying on a succession of medicines without end, neglect, in spite of every exhortation and every indication of reason, the best

tonic and nervous medicine of all, and one which they can always procure by slight exertion—we mean the cool and pure air of the earlier hours of the day. If they cannot deny the unfavourable influence of passing twelve hours out of every twenty-four in the close atmosphere of a bed-room, the conviction has seldom any effect upon their habits. To supply the strength thus lost, recourse is had to various stimulants, and the result is often the total destruction of health and comfort, and the conversion of all the years after forty into “a long disease.”

The effect of various impressions on the mind is always to be considered in cases of benefit derived from change of air. A sea-voyage, therefore, or a journey attended with many incidents, and with some difficulties, has sometimes been found to be very serviceable. The wives of officers, delicate and hysterical in the languor of country quarters, have lost their complaints amidst the fatigues or dangers of a march. The ladies of Paris forgot their hysterical affections, we are told, in the French revolution, and the Irish ladies in the rebellion, although exposed to many and violent impressions. Cullen noticed similar effects in the ladies of Scotland in the civil war of 1745-46; and Dr. Rush, in a curious paper “On the Influence of the American Revolution on the Human Body,” says that many hysterical women, who were much interested in the successful issue of the contest, “were restored to perfect health by the events of the time, change of place, occupation,” &c.* Dr. Parry has recorded some remarkable instances illustrative of the same principle;† and Dr. Bright observes that a severe nurse in a ward will sometimes cause hysterical disorders to be less inveterate there than in other wards.‡

Ease and indulgence seem always to exasperate this disorder. The daughters of cottagers removed to the kitchens of people in comfortable circumstances, often become hysterical. The wives of merchants, Frank remarks, are affected with hysteria in flourishing times; but when reverses come, they “have no time to be ill.”§

In both classes of cases the treatment of which has now been spoken of, periods occur in which neither the proper remedies for plethora, nor those usually suitable to states of mere debility, will do all that is required. The plethoric tendency may be controuled, and the susceptibility, the tendency to irregular and spasmodic actions, yet remain; and the same may be the case both where every thing has been done to counteract debility, and where the patient, although manifestly weak, cannot bear many of the usual means of restoring the strength. It is in these cases that a watchful practitioner will find periods in which anti-hysterical, or antispasmodic, stimulant, or seda-

tive medicines, may be prescribed with the happiest results. We do not here so much allude to opium, henbane, conium, and medicines of that description, which are generally only given with temporary advantage in cases of hysteria; but to assafoetida, musk, valerian, and other means which appear to be not only antispasmodic, but directly to decrease the morbid susceptibility of the nervous system. First in the list we should place the gummi resina assafoetida, the chief of those “fetid medicines” which, in the language of Sydenham, “are calculated to compose the tumultuary motion of the spirits,” and were therefore anciently called *hysterics*. The assafoetida is, indeed, a medicine which we have found particularly useful; and, if the patient will submit to take a very nauseous mixture, the *mistura assafoetida* (the old *milk* of assafoetida) is perhaps the most efficacious form in which it can be given. Each ounce of this mixture contains gr. xv. of the gum resin, and either $\mathfrak{z}\text{i}$ or $\mathfrak{z}\text{ss}$ may be given three or four times a day, in cases in which the patient is subject to very frequent attacks. It is, however, often necessary to give this disagreeable medicine in pills: in either form much confidence may be placed in it. If genuine musk could commonly be procured, its prescription in doses of gr. xv. three times a-day would probably be equally or even more efficacious: it is certainly a valuable medicine. The *mistura moschi* of the pharmacopœia, containing in each $\mathfrak{z}\text{ss}$. of aq. rosæ gr. xv. of musk, is one of the most convenient formulæ for the use of the practitioner. The utility of both the assafoetida and the musk will be the most conspicuous in cases in which the surface is pale and the pulse languid. The castoreum has been much recommended; and the tincture, and still more the compound tincture of the Edinburgh pharmacopœia, in which it is combined with assafoetida, may be usefully added to other medicines in doses of one or two drachms. The effects of valerian are occasionally very striking. Idiosyncrasies seem to exist, which render different anti-hysterical medicines of paramount service in different cases; and in some of the forms of hysteria the valerian is a specific. As many patients cannot bear the powder, the *infusum valerianæ* of the pharmacopœia of Dublin may be conveniently prescribed: we are ourselves most familiar with its effects in the form of the *tinctura valerianæ ammoniata*; and particularly in the hysterical headach, to be presently spoken of. The *oleum succini* has sometimes been recommended in hysteria, but we do not think that either in its simple form, or in that of the *spiritus ammoniæ succinatus*, it is now much employed.

Although we feel convinced that there are, as we have said, periods in almost all cases in which antispasmodics are most serviceable, there are no medicines which will more surely disappoint the practitioner who trusts entirely to them, or employs them indiscriminately. In many cases it must be remembered that the means of reducing vascular action, or, on the other hand, the means of improving the general strength, are the best antispasmodics, and

* Medical Inquiries and Observations, vol. i, Philadelphia and London, 1794.

† Posth. Works, vol. i, p. 368-9.

‡ Op. cit.

§ Op. cit. cap. xiv.

more truly anti-hysterical than any specifics which can be employed.

The restless nights and various uneasy feelings of hysterical patients make it in many cases absolutely necessary to have recourse to anodynes. The extracts of hyoscyamus and conium, with camphor; the tinctura opii, or tinctura camphoræ composita; the acetate or muriate of morphia, the liquor opii sedativus, the Dover's powder, or opium alone, will be suitable in different circumstances: but the disposition of hysterical patients to continue the use of these medicines, and to take them in large quantities, should be carefully discouraged.

Treatment of cases dependent on uterine disorder.—Independently of all the parts of the general treatment of hysteria, these cases require especial attention, different according to the precise disorder existing in the uterus. If amenorrhœa is present, which we have stated that we consider *not* a very common circumstance, the practitioner must have recourse to the proper treatment as described under that head. (See AMENORRHOEA.) If, as more frequently happens, there is too frequent or too copious menstruation, a form of disease in young females which is even more difficult to be managed, attention to the general health will be found the most important; although sometimes astringent medicines are decidedly useful. We have known marked advantage derived from taking six or eight grains of the pulvis kino compositus with a few grains of alum two or three times a-day; but when medicines of this kind are given, the supervention of headach, with a hot and dry skin and feverishness, will sometimes compel their discontinuance. There is usually in such cases what may be termed an irritable state of the uterus, indicated by pain in the hypogastric region, in the sacrum, along the upper edge of the ossa ilia, and down the thighs; with leucorrhœa, and a quick and feeble pulse: the os uteri is tender to the touch, and there is a disposition to organic disease: the digestive organs are almost always in these instances considerably disturbed. Cupping on the loins, leeches to the epigastric region, or to the vagina or the os uteri itself, anodyne enemata, fomentations, rest in the horizontal position, the frequent use of the hip-bath, and temporary separation a marito, and a most careful avoidance of irritating purgatives, are among the measures most to be recommended in such cases. For the addition of anti-hysterical or tonic remedies no rules can be laid down; the judgment of the practitioner must entirely regulate their administration in each case: they will often be found necessary even when the uterine irritation is relieved.

Some of the French practitioners lay more stress than we are accustomed to do in this country on particular articles of diet, and substances introduced in enemata, in occasioning uterine excitement and hysteria. Crabs, mussels, onions, truffles, aromatic chocolate, vanilla, and cinnamon, are enumerated by M. Louyer Villermay as having these effects; and he adds

perhaps strawberries and raspberries, but more certainly too nourishing, spiced, and heating aliments, wines, spirits, and every excess. He further mentions pastilles, into the composition of which the powder or tincture of cantharides enter; and also enemata of drastic, irritating, and poisonous plants, which he says have often caused nymphomania with convulsions, terminating in death.*

Treatment of cases dependent on gastrointestinal disorder.—These cases may require little more than the simple treatment of indigestion (for which we refer the reader to the article INDIGESTION) as preparatory to the administration of antispasmodic medicines. If there is much tension of the abdomen, with uneasiness, and some tenderness on pressure, the cure will be very much hastened by the application of from six to twelve leeches to the epigastrium. This practice, recommended by Dr. Wilson Philip in particular stages of indigestion, we have seen the immediate advantage of in innumerable instances; constantly observing the utility of medicines after such application, which had been fruitlessly persevered in before. If the lower part of the abdomen is tumid and uneasy, the leeches may with more advantage be applied to the orifice of the rectum. But this tenderness is by no means constant in hysterical cases; and the distention of the abdomen is seldom permanent, but rather comes on and subsides with some suddenness, and is then shewn by many symptoms to be dependent on flatus. Temporary relief may be obtained in the attacks from carminatives; as the compound tincture of cardamoms in aqua menthæ piperitæ, aqua carui, or aqua cinnamomi, or a little spiritus ætheris aromatici in camphor mixture; or even a few drops of the oleum carui on sugar. The importance of giving relief in these attacks of flatus depends less on their severity, although that is considerable, than on their tendency to induce the hysterical paroxysm. The measures from which we have seen the most permanent efficacy are the administration of the warm gums and purgatives at night, or night and morning, and of bitter medicines with an alkali twice a day; with strict attention to diet and to clothing. Eight or ten grains of the pilulæ aloes et assafœtidæ of Edinburgh, or equal parts of the compound extract of colocynth and of the pilulæ galbani compositæ, have seemed to be of essential service: the inactivity of the bowels often requires an aperient draught to be given in the morning; in which case the decoctum aloes compositum is preferable to salts and senna. Whytt recommends pills of assafœtida, extract of aloes, and sulphate of iron: we have found pills of the sulphate of iron, extract of aloes, and extract of gentian, very beneficial: the tinctura muriatis ferri, or a draught of equal parts of infusum gentianæ compositum and aqua menthæ, with the carbonate of potass or of soda, twice a day, are also useful. The state of the stomach and bowels is often improved by giving small

* Dictionnaire de Médecine, Art. *Hysterie*.

alterative doses of the pilula hydrargyri; but the practitioner should never forget, that although nervous patients are more than all others sensible of the immediate relief derived from taking a dose of the blue pill or of calomel, there are none on whom the penalties of taking these medicines too often or in excess, are more certainly and more painfully exacted, in the shape of increased nervous susceptibility, which may thus indeed be exasperated to the extremest sensitiveness, and even to madness.

External applications, in the form of emplastra, are perhaps too little regarded in modern practice; we are persuaded that much benefit is sometimes obtained by the application of a good-sized emplastrum galbani compositum to the abdomen, as well as occasionally by a mercurial plaster. A broad bandage of flannel is sometimes useful, and the daily use of the flesh-brush and friction. We have not found any form of bathing very serviceable in this description of cases.

Attention to the diet of these patients is of great importance: they generally find it necessary to avoid fluids and vegetables, except in small quantities. Moderate meals, at regular and sufficient intervals, should be recommended to them, rest in the horizontal position for an hour after eating, and afterwards exercise: a glass or two of sherry after dinner will generally be found useful to them, or small quantities of brandy and water. Porter, ale, and beer, seldom agree with them. One of the benefits of not drinking at dinner, a rule in itself not warranted by natural instinct, is that it causes the patient to eat less: large draughts of beer or soda water are decidedly improper.

If there is reason to suppose that the hysteria is almost wholly dependent on confined bowels, the continued use of the compound aloetic pills will perhaps be found more productive of relief than the most complicated treatment which can be devised. Large and unsuspected collections of fecal matter are frequently lodged in the colon, and remain or re-accumulate, unless the practitioner perseveres in the treatment calculated to remove them.

When the hysteria is connected with the presence of worms in the stomach or bowels, recourse may be had to anthelmintics: except in the case of tænia, however, against which the oleum terebinthinæ may almost be said to be infallible, the best vermifuges will be found in the means already detailed.

Among the complications of hysteria we have already mentioned that of the intestinal with uterine irritation; and the cases which we have just described will often be found to be considerably aggravated at the menstrual periods. We are convinced, however, that in many such examples the uterine irritation is neither first in order nor in importance. No sequence is, in fact, more familiar in pathology than that of irritation of other mucous membranes supervening on that of the intestinal canal.*

The vehement pulsation of the aorta, which was also mentioned, sometimes depends on intestinal disorder.

Treatment of particular symptoms.—Concerning these it will not be necessary that much should be added to what has already been laid down respecting treatment; but the practitioner will be disappointed if he looks for the retreat of some of these troublesome complaints even when attacked according to all the rules of art. Theoretical writers, vain of their science, but unversed, as it would appear, in the perplexities of practice, are too ready to deride empirical modes of relief, and to believe that their general maxims are all comprehensive. Thus M. Louyer Villermay, maintaining the uterine theory, disregards the condition of other organs; and M. Georget, treating the uterine theory with ridicule, asserts that as hysteria is a disease of the brain, it is idle to prescribe for the stomach, or the heart, or the lungs; and seriously advises "pills of crumbs of bread and other substances of like energy, and for drink, water and tisanes of equal virtue." Whoever sees much of hysteria will soon become satisfied that such practices would be singularly useless, and that even when every general means has been attended to, there are particular attentions which cannot be neglected without disadvantage.

The hysterical headach is best relieved by the tinctura valerianæ ammoniata in doses of ʒiʒ, with an equal quantity of sp. æth. sulph. comp., or of sp. lavand. comp., or of the tincture of hyoscyamus, in camphor mixture. A drachm of the simple tincture of valerian, and ten or fifteen drops of acidum sulphuricum dilutum, taken twice a day, with or without ʒi of the tinctura cinchonæ, is also a useful medicine. The application of cold to the head, the frequent use of the shower-bath, and of pediluvia of warm water, may be resorted to with benefit. Although blisters behind the ears are in these instances, and in those of hysterical pains about the face, usually productive of much temporary irritation, their employment is often followed by relief. In very obstinate pains, as in nearly all obstinate chronic disorders, a gentle course of mercury has occasionally proved useful.*

For the relief of those cases in which the symptoms of phrenitis are simulated, rest, quietness, opiates, and, according to circumstances, purgatives, and the usual means of equalising the circulation, will generally be found efficacious; and stronger measures are not hastily to be resorted to.

In the hysterical asthma, in addition to the ordinary treatment of cases in which there is much nervous irritability, the patient may take pills of equal parts of ammoniacum and squill, or of ammoniacum and assafetida. Dr. Whytt recommends equal parts of the two latter in aqua pulegii. We have seen evident relief from plasters of assafetida and ammoniacum applied to the chest. These cases also often require particular attention at the monthly

* The reader is referred for an illustration of this important principle to the article ASTHMA, vol. i. p. 194.

* Whytt.

periods, when small doses of the sulphas magnesiae, with the tincture of hyoscyamus, given in the mistura camphoræ, will sometimes be found to ward off threatening symptoms.

Of all forms of hysteria none are so obstinate as those attended with pain in the left side. We have not found it so constantly connected with tenderness of the spine, nor so uniformly dependent on uterine disorder, as Mr. Tate seems to have done. As regards all local treatment of the side itself, we believe it to be a mere waste of time; nor can we speak with much confidence of medicines. We have generally found it difficult, sometimes impossible, to produce proper counter-irritation in the side; but, on the whole, have seen more advantage gained from repeated applications of the tartar emetic ointment to the spine than from any other means. After many trials, we prefer using ointment of the strength of a drachm of the antimonium tartarizatum to 3ii or 3iii of cerate; one application, the part being previously sponged with hot vinegar, being often sufficient to produce numerous small pustules, by the repeated evocation of which we have thought the patient much more benefited than by the same counter-irritant applied as a plaster or in any other degree of strength. In our experience, the advantage derived by the patient from the use of this ointment is not generally increased in proportion to the suffering it occasions. Leeches, and a succession of small blisters to the spine, are in some cases still more serviceable than the ointment.

These cases are very unsatisfactory. The patient sometimes continues an invalid for one or two years, and at length recovers without appearing to be under much obligation to medicine; or sinks into a state of atrophy, hardly able to take any nourishment, a prey to every morbid feeling, and a burthen to herself and to all about her.* The tenderness of the dorsal spine and the pain about the sacrum have been accurately pointed out by Mr. Tate, who has also given some very striking cases in which relief followed his practice in them. Dr. Darwall had previously called the attention of the profession to the tenderness and spinal irritation, and Mr. Griffin has published some interesting cases of it in the *London Medical and Physical Journal*. Mr. Tate apprehends that the accompanying pain in the side is seated in the intercostal nerve; although he says he has sometimes thought it must be situated in the nerves of the heart itself. The right side, however, is occasionally the seat of suffering; and we have not observed that the pain, even when in the left side, was often attended with palpitation: a sense of weight is very commonly complained of. We have proposed acupuncture with sanguine expectations of success, which have ended in disappointment. In one case we noticed complete relief ensuing on the coming out of a vesicular eruption in the situation of the pain, and in

another on the appearance of an ovoid tumour, which subsequently subsided without suppuration. Dr. Whytt, to prove that "complaints of the nervous or hysteric kind often proceed from some morbid humour in the blood," adduces cases in which "an itching between the toes, red pustules appearing on the breast and belly, or some other cutaneous eruption," produced relief.* Much of the difficulty in these peculiar cases arises from the morbid state of the patient's mind: she supposes that she cannot walk or move, or bear the shower-bath and other means; and the kind attentions which it would be inhumanity to withhold from such apparent afflictions seem to make them more intractable.

Hysterical palpitation is often almost instantaneously relieved by the valerian, or yields to its more continued use. The danger of repeated bleedings in these cases is extreme, or, at least, the mischief thus induced is incurable. The hysterical diabetes will probably be best treated by opium, blisters, or plasters to the loins, flannel worn next the skin, and other parts of the general treatment: spurious symptoms of calculus in the ureters will yield to anodynes and laxative enemata; and attention to the state of the bowels and surface will best keep off the attacks. The great violence of the pain in these cases sometimes leads the practitioner to use the lancet and other means, which are generally superfluous and often very detrimental to the patient.

In the mutable cases, in which various diseases seem to succeed each other with rapidity, each new aspect of the malady may require new resources; but the general principles of treatment must be kept steadily in view.

We have not spoken in this article of electricity, galvanism, or electro-galvanism, agents which have occasionally been employed in the cure of hysteria; we fear that their application has hitherto done little more than prove the inveteracy of some forms of the disorder. (See *ELECTRICITY AND GALVANISM*.)

It may here be observed that hysterical women are very generally disqualified for being good nurses. Sometimes the performance of that function may be serviceable to them, but they generally perform it inefficiently; their liability to feel all impressions too keenly, and the violent agitations of feeling and temper which belong to them, operating unfavourably on the secretion of milk, and causing disturbance in the child's bowels, and perhaps in its nervous system.

No part of pathology or practice is more unsatisfactory in its present state, or at the same time more promising of future results, than that which relates to the conditions of the blood. If any cases of hysteria could be clearly traced to peculiar states of that fluid, productive of nervous irritation, the object of our treatment would of course be to effect an alteration in it. The means of doing so would be the regulation of diet, the improvement of the digestion, attention to any function obviously deranged,

* For an extreme example see Dr. Bright's Reports of Cases, vol. ii.

* Op. cit. chap. iv.

and a careful general regimen. The effects which have ensued in some recent experiments in which saline substances have been directly injected into the veins, would seem to point to very important results. And if the practitioners residing at watering-places had been less satisfied with general assertions of the universal virtues of the mineral waters of their respective localities, and more observant of the actual operation of these serviceable agents in chronic maladies, reasons might have been found for ascribing some part of the benefit derived from them to their effects on the circulating fluids rather than on the bowels, effects which have long been admitted in the case of the chalybeates, but hardly ever hinted at as regards the saline waters. We should desiderate, however, the perfect establishment of facts indicative of such advantages before we should be disposed to send hysterical, and fanciful, and susceptible patients to places resorted to by so many whose idleness and selfishness are their chief complaints. It is not in places devoted in an especial manner to every weak and luxurious indulgence, and in which the honours of medical science cede too often to a miserable waiting upon the caprices of spoiled adults, that we can expect hysterical females to acquire habits of bodily or of intellectual health.

Preventive treatment.—When a young lady has had an hysterical attack of some severity, much anxiety is commonly felt to prevent a recurrence of it; and this may in the generality of cases be thus early prevented by proper attention to the causes which appeared to bring on the attack, and to any peculiarity in the state of her health which has predisposed to it. Where there has been no severe and marked paroxysm, and yet many of the peculiarities of the hysterical temperament exist, the preventive treatment is too often neglected, whilst in the examples in which it assumes peculiar and embarrassing forms, the nature of the disorder is often misunderstood, or, after very insufficient trials, medical and moral means of relief are abandoned.

A careful education may undoubtedly prevent the increase of a susceptibility observed to be naturally too intense; but, although it would be easy to lay down regulations for the accomplishment of so desirable a purpose, it would manifest a great want of experience in the ways and weaknesses of mankind to expect such regulations to be followed with much perseverance. As regards schools, however, it is but just to acknowledge that of late years much more attention has been paid to allowing hours for relaxation and exercise than formerly. Yet the exercises of ladies' schools are often absurdly enough ordered; the natural amusements of running, leaping, and playing at various active games in the open air being considered ungentle, and, by a strange inconsistency, the rigid positions of the drill sergeant, the fixed distortion and torture of the feet in stocks, as inculcated by dancing mistresses, the difficult poises and attitudes of a system which is termed calisthenic, and some-

times the exercises of tumblers, the climbing of ropes, and the rubbing of tables, are among the approved means of avoiding at once both deformity and the vulgarity of rude and boisterous health. Meanwhile, the nature of their studies is such as hardly to merit the name of mental cultivation. Ostentatious efforts are made to crowd the elements of many accomplishments into a few years, and if the young lady is not afterwards *finished* by those who profess to instil taste as well as art, and who succeed in effacing all natural and simple tastes and traits of character, she commonly remains unskilled even in accomplishments; whilst the want of all love of literature or acquaintance with science, and consequently of all companionable qualities of a higher kind, diffuses an ennui over society that every one feels without thinking of its source, and by which the whole moveable community is driven about from one place of public resort to another, without useful objects, without attachments, without duties; leading to the habitual neglect of all self-government and the creation of much domestic wretchedness. After the confinement of school, the young female is introduced into fashionable life, and exposed to numerous causes of debilitated health. Returning for a few seasons to London blooming from the coast or the country, she leaves town in June the shadow of herself, often bearing in her countenance not only the marks of dissipation, but of expectations disappointed, wounded pride, and a disposition from which all the attractive frankness of youth has been carefully rooted out. Then, perhaps, ensue the mortifications of celibacy, and the misery of growing old without an active and contented mind. Concerning the evil effects of these and many other circumstances, the physician may feel a thorough conviction, but as the circumstances are not much within his controul, it would be useless to dwell upon them in the present article. As causes of disease, and especially of hysterical and other various disorders, none will deny their wide and powerful influence but those who have paid no reflection to the operation of human passions in society. From the circles of nobility these follies flow to the families of the country gentry, and from them to the upper ranks of country towns, whose inferiors of every degree imitate them as well as their daily necessities will permit. The dictates of health, of reason, of happiness, are lost in the love of false greatness and over-refinement which hangs over empires devoted to decay. But against such habits it avails little to protest; the physician cannot obviate them, nor are they "curable by any herbs."

He may, however, often with more success devote some portion of his care to the preservation of a healthy body. If every function is well performed, the nervous system will, it is probable, soon become freed from the morbid susceptibility which disposes the young female on receiving any slight impression to the irregular actions of hysteria. It has so often been found useful in chronic disorders of

an obstinate nature to place the patient in new circumstances, and thus to change the whole series of impressions to which she is exposed, that this resource should not be overlooked. With this intention the hours of rising and taking food, the times of exercise and rest, the nature of the mental occupations and of the bodily exercises, should no longer be the same as customary. Change of scene, change of climate, change of manner of clothing, may all form parts of such a plan. So many of these changes are effected at once by a removal to a watering-place, or to the sea, that the advantage of such a change may overbalance all other considerations, and be advised with great propriety.

Nor should it be forgotten that the different parts of what is called an alterative treatment often induce most important changes by slow operations, seemingly effected in the actions or condition of the nervous or vascular systems, or wrought upon less obvious sources of continued malady, existing perhaps in the secretory processes. (See ALTERNATIVES.)

By the means now enumerated, numerous, as always happens in diseases little obedient to the healing art, and requiring consequently much discrimination in the practitioner who employs them, there is no doubt that many cases of hysteria may be completely cured, and that almost all cases may be more or less relieved. The constitutional susceptibility in some instances of the disorder is so great that relief is all that can be effected, and the protracted character of the malady often leads to its being too soon withdrawn from the care of the physician. Where this is not the case, we believe the failure of the treatment is generally to be ascribed to a want of patience, an insufficient employment of the various resources which we possess, or a want of conformity and perseverance on the part of the patient herself.

Even a palliative treatment, if nothing more can be immediately promised, should not be disregarded either by the patient or the practitioner, it being unquestionably true, as Dr. Whytt has remarked, that "long-continued palliation may sometimes make a cure; for while the palliative remedies lessen the bad effects of this disorder of the nerves, nature, either by herself or with their assistance, at length expels or subdues the morbid cause." The practical wisdom of this observation may be remembered with advantage in the treatment of all chronic diseases.

We have dwelt longer on the affections united under the name of hysteria than we should have done if we did not know that it is always a peculiar disadvantage to the practitioner to decide, or to be expected to decide, at once upon a plan of treatment of which the immediate effects are to be observable in each hysterical case. It seemed to us that their proper treatment might be facilitated by considering them with reference to their various origin and complications somewhat more closely than had before been done. The best chance of effecting a perfect cure in any

case will depend on the deliberation with which all the circumstances connected with it are considered: the origin, the causes, the duration of the malady, and the present state of the patient, well and duly reflected upon, will usually lead to means of eventual relief, to which hasty and presumptuous prescription can seldom or never attain.

(J. Conolly.)

ICHTHYOSIS,* (from *ἰχθυς*, a fish,) *fish-skin*, a cutaneous disease, named from its supposed resemblance to the skin of a fish. In our opinion, Willan and Bateman have erred in classing it in the order *Squamæ*, as it has a much nearer affinity to the papular than to the scaly eruptions. It is characterised by a harsh, papillary, or horny condition of the skin. In other instances, the papillæ are elongated into horny peduncles bearing a broad irregular top. Whatever be the cause of this morbid growth, it appears to have a close affinity to that state which produces the common wart. These excrescences frequently suffer partial exfoliation, which affords the scaly appearance that probably may have led to the present arrangement of the disease.

Instead of the division of the genus into the two species, *ichthyosis simplex* and *ichthyosis cornea*, it would be more consonant with experience to divide it into, 1. *ichthyosis fortuita*; and, 2. *ichthyosis innata*.

In both species of the disease the eruption sometimes appears on distinct portions of the body, whilst the rest of the skin retains its healthy appearance; sometimes it extends over the whole of the surface, except the hairy scalp; and although it is observed directly above and below the flexures of the joints, yet it seldom appears on or around the joints, or, as Dr. Bateman remarks, on the inner and upper parts of the thighs. It also rarely appears in the axillæ, upon the palms of the hands, or on the soles of the feet.

Species 1. *Ichthyosis fortuita*, (*ichthyosis simplex* of Willan and Bateman) not unfrequently affects only the extremities, and occasionally the face. The more extended form of the disease is common in children who come from India at rather a later period than usual. It rarely makes its appearance for the first time in adults, and appears to commence by a soiled appearance of the cuticle, followed by a thickened, papillary, and discoloured condition of the skin, which seems, to a casual observer, the effect of want of cleanliness. By degrees the hardness and roughness increase, so as to afford to the finger, when passed over the skin, the sensation caused by a rough file, or shagreen. The colour of the patches soon deepens to a dirty, brownish-black hue; and when carefully examined, they are found to be composed of small pedunculated horny excrescences, closely impinging upon one another; or, when the disease is general over the body, of conical horny excres-

* *Syn. Lepro ichthyosis* (Saww.); *Lepidosis ichthyosis* (Young, Good).

cences, the apexes of which are generally loose and separating, so as to give the appearance of being covered with dirty, coarse meal. In some instances these horny papillæ are crowded in various groups, following the variations of the cuticular lines: in other instances they form decided patches, like incrustations upon the part; and when the peduncles are long, and the clothes press upon the parts, the papillæ overlay one another like scales; but in no case do they naturally assume an imbricated or scaly aspect. The patches are occasionally separated by whitish furrows; in some cases, when they are distinct, they terminate abruptly, in others they are gradually lost in the healthy skin. When the face is the seat of the disease, it is usually confined to the cheeks; but in a case mentioned by Dr. Bateman,* and another, in a young lady, which came under our own care, the patches on the cheeks communicated across the nose, so as to produce the appearance of a pair of large brown spectacles laid upon the face:† in some instances the mammæ in females have appeared completely encased in this horny covering. If the excrescences be picked off, or if they fall off when submitted to the action of the vapour of hot water, they rapidly grow again; but, in the interim, the skin does not bear any trace of inflammation; it appears in a healthy state until the papillæ re-assume their former horny aspect. In the case of the young lady referred to, the disease, which made its appearance about the age of puberty, was preceded by considerable constitutional disturbance, namely, headach, disordered bowels, cold feet, and flushings of the face; but in general no premonitory symptoms have been observed; nor is the eruption accompanied with itching, tingling, or any uncomfortable feelings. The whole skin, in the more extended form of the disease, is dry, and its perspiratory function apparently impeded; it has been suggested that the urine and the pulmonary exhalations balance the defective perspiration, and maintain the general health of the habit.‡ Biett mentions that in some instances the sound or uncovered parts of the skin perspire more than usual.

Few opportunities of ascertaining the condition of the constitution or that of the skin in this disease, have occurred to us; but the few which have presented themselves have confirmed the view we have given, namely, that it cannot be regarded as a scaly eruption. The chorion is found to be thicker than usual, and the furrows which traverse it are deeper than common: the horny papillæ are readily detached by maceration. But these investigations have shed very little light upon the nature of the disease.

Treatment.—The obstinate nature of this eruption has in many instances resisted every plan of treatment, both local and general. With the exception of the decoction of the root of rumex

obtusifolius, no internal remedy appears to have at any time produced benefit. The decoction of this dock root, made with an ounce of the sliced root and a quart of water, boiled down to a pint, and taken in doses of a fluid ounce and a half twice or three times a day, purges briskly, and clears the skin in ten or twelve days; but in cases of long continuance the eruption is likely to return. Dr. Willan strongly recommended pitch, made into pills with flour or some farinaceous matter; the dose being gradually increased until twenty or thirty of the pills are taken in the course of the day. The pitch seems to operate by stimulating the capillary system, so as not only to enable the skin to throw off the patches of horny cuticle, but to restore the skin to its natural and healthy state.* Arsenic is sometimes useful on the same principle; but the experience of those who have had the best opportunities of seeing and treating the disease, affords little encouragement to prescribe it. The dock-root, the use of which was first recommended by the writer of this article, is certainly the most effectual remedy which has been hitherto employed: the only objection is its disposition to purge, which, however, can be moderated by the addition of ten or twelve drops of laudanum.

In old cases, when the eruption returns, and is successively removed by the decoction of the dock-root, the obstinacy of the case often depends upon a state of the skin which is sometimes only to be permanently relieved by the application of blisters over the whole of the diseased surface; this was the case in the instance of the young lady already mentioned.

With regard to external means, almost every stimulant and detersive plaster and ointment has been tried, and each in its turn declared nugatory. The scales have been picked or shaved off, and removed in various ways, but in the greater number of instances without any permanent advantage. Mr. Plumbe found the firm application of adhesive straps aid greatly the desquamation, if this term may be employed, of the patches; the diseased cuticle was softened, and might be scraped off without pain. "By persevering," says Mr. Plumbe, "in this plan, the skin gradually acquires a healthy texture."† Sulphur fumigating-baths have been found useful, and the benefit received is undoubtedly more permanent than when the common sulphureous baths of Harrowgate, or similar springs, are employed; but, nevertheless, in several instances in which we have seen the fumigating baths used, the eruption has returned after they were discontinued. Whatever applications are used, the daily employment of the warm bath, with friction whilst in the bath, and brisk exercise taken immediately afterwards, materially aids the restoration of the healthy condition of the skin. The bath should be used in the morning.

* Dr. Willan generally ordered at first three or four five-grain pills to be taken three times a day; and the number of pills to be gradually increased until a drachm of the pitch was taken for a dose.

Species 2. *Ichthyosis innata*.—This congenital form of ichthyosis, although scarcely perceptible at birth, yet even at that period may be recognised by the skin being harsher and thicker than usual in infants, and rough when the finger is passed over it. By degrees, as the infant grows, the disease assumes its proper character. In almost every recorded instance the disease has been hereditary. As in the fortuitous species of the disease, the rigid and scaly state of the skin is sometimes partial, sometimes general, assuming the appearance as if the body was covered with a coat of mail. The case of the native of Suffolk, known by the name of the "Porcupine Man," and described by Mr. Baker in the forty-ninth volume of the Philosophical Transactions, is the best illustration of this form of the congenital disease. The face, the palms of the hands, and the soles of the feet, were the only parts free from the scaly covering. The disease appeared about two months after birth, and the scales regularly dropped off every winter and re-appeared in the spring. The individual enjoyed excellent health, and had six children, all of whom were covered with the same excrescences. Many other curious examples of congenital ichthyosis are to be found in the Royal Transactions and the memoirs of the various scientific societies throughout Europe; but as no means that have hitherto been tried have proved successful in restoring the healthy texture of the skin, it is unnecessary to refer to them.

The ichthyosis *cornea*, horny fish-skin of Willan and Bateman, the *cornua cutanea* of Plenck,* the *appendices cornés* of Rayer,† has been improperly confounded with the congenital form of ichthyosis by Bateman and Rayer; but the horny appendages constituting this affection, which cannot be regarded as a species of ichthyosis, are rarely if ever congenital, and differ in every respect from the horny papillæ of ichthyosis. "They are," as Bateman expresses himself, "purely of cuticular growth, consisting of a laminated callous substance, contorted and irregular in form, and not unlike isinglass in appearance and texture." In every instance they are accidental, and generally connected with some diseased growth, such as wart;‡ or they arise in the cavity of encysted tumours of very slow growth. Their extirpation belongs to the province of surgery; the only effectual remedy being excision and the ample destruction of the surface secreting them, at an early period.

(A. T. Thomson.)

ICTERUS.—See JAUNDICE.

IDENTITY, PERSONAL.—The question of personal identity becomes not unfrequently a matter of vital importance in both civil and criminal investigations.

* Doctrina de morbis cutaneis.

† Maladies de la Peau, tom. ii. p. 315.

‡ Morgagni, de Sedibus et Causis Morborum, ep. 65, art. 2. *Avicenna*, canon. iv. fen. 7, tract. iii. cap. iv. *Lorry*, de Morbis Cutaneis, p. 519.

1. Thus it may be doubted whether a child claiming an inheritance is the same that he pretends or is pretended to be, as in the celebrated Douglas* or Anglesea† causes; or long absence of the owner of property may give rise to a similar doubt, as happened in the following instance related by Zacchias.‡

A noble Bolognese, named A. Casali, left his country at an early age and joined the army. He was supposed to have lost his life in the wars; but after an absence of thirty years he returned and claimed his property, which his heirs had already appropriated to themselves. Although there were some marks which appeared to identify him, yet the change in appearance was so great, that none who remembered the youth were willing to allow that this was the individual. He was arrested and imprisoned. The judges were in great doubt, and consulted Zacchias whether the human countenance could be so changed as to render it impossible to recognise the person. His opinion was in the affirmative; in consequence of which, and because the heirs could not prove the death of Casali, the judges restored to him his name and estates.§

Thus it might happen that the true heir would not be able to prove his right merely by failing to establish his identity; while, on the other hand, an impostor may succeed where he has no claim, merely by the force of resemblance. One of the most remarkable instances of such an occurrence is that of Martin Guerre, which came before the parliament of Toulouse in 1560.

Martin Guerre had been away only eight years, when a certain Arnauld Dutille, depending on his likeness to the absent person, formed the design of taking his place, and actually took possession of the property and wife of the true Martin. Children were born of this union, and he lived in the family more than three years, with the four sisters and two brothers-in-law of Martin, without being suspected. At length, however, it became matter of trial, and three hundred witnesses were examined; thirty or forty of whom deposed that the new comer was really Martin Guerre, with whom they had been on habits of the closest intimacy. Nearly an equal number swore that he was Arnauld Dutille; while the others were so perplexed by the resemblance between the parties that they would not venture to affirm whether the individual before them was the one or the other. The judges also were completely puzzled, and were on the point of deciding in favour of Dutille, when the arrival of the true Martin exposed the imposture; though to the last the effrontery and impudence of Dutille led many to doubt, and even Martin himself appeared confounded;

§ See also Foderé, vol. i. p. 109.

so that the judges were still more embarrassed than before his arrival. At last, however, he was fully identified and recognised by his wife and sisters.*

2. Secondly, in criminal prosecutions the question has very frequently arisen, whether a prisoner is actually the person who committed the offence with which he stands charged; or, where a prisoner after conviction escapes and is retaken, whether he is the same person that was convicted. The same question also applies in cases of return from banishment.

In connexion with this branch of the subject, circumstances have repeatedly occurred evincing the vital importance of the accuracy which should furnish grounds of evidence; and the extreme caution by which witnesses or prosecutors should be guided in depositions. A few years since a gentleman coming into Dublin late in the evening, was stopped and robbed by a footpad. A man was arrested by the police under suspicious circumstances, and, being recognised by the gentleman, was committed to abide his trial, when he was identified by the prosecutor in the most positive manner; in consequence of which he was found guilty, but, owing to previous good character, recommended to mercy. In a very few days afterwards, the gentleman was surprised and horror-struck at meeting on the road the man who had really robbed him.

The mistake here appeared to arise from the imperfect light in which the robbery had taken place, and naturally suggests for our consideration a question which has given rise to some discussion, and appears to require notice here, viz. *the degree of light which may be necessary to enable an observer to distinguish the features, so that the person may be afterwards identified.*

In a case which occurred in France in 1809, of a person shot at night, it was stated that the flash of the pistol enabled the witness to identify the features of the assassin. The possibility of this was referred to the Institute, who reported against it. Foderé, on the other hand, believes that if the persons be at a small distance from each other, and the night very dark, such an event might be by no means impossible.

A case in point occurred in England in 1799. A man named Haines was indicted for maliciously and feloniously shooting at Edwards, Jones, and Dowson, Bow-street officers, on the highway. Edwards deposed that, in consequence of several robberies near Hounslow, he, together with Jones and Dowson, were employed to scour that neighbourhood; and that they accordingly set off in a post-chaise on an evening in November, when they were attacked near Bedfont by two persons on horseback, one of whom stationed himself at the head of the horses, and the other went to the side of the chaise. The night was dark; but he swore that, from the flash of the pistols, he could distinctly see that the man rode a dark-brown horse between thirteen and fourteen

hands high, of a very remarkable shape, having a square head and very thick shoulders; and altogether such that he could pick him out of fifty horses: he had afterwards recognised the horse. He also perceived, by the same flash of light, that the man at the chaise-door had on a rough-shag brown great coat.

A lady, a patient of the writer, lately told him that on one occasion, on her passage from India, she awoke in the middle of the night and heard some one stirring in her cabin, but could see nothing, it being quite dark; when suddenly the cabin was so completely illuminated by a flash of lightning, that she could see distinctly a man rummaging one of her trunks, and discerned his features so accurately that she identified him next morning: some of the stolen things were found upon him, and he subsequently acknowledged the fact.

We were once present at a trial when a witness swore that the prisoner at the bar was one of a party who attacked and burnt his house, and that he saw him, at a distance of more than ten yards, in the act of putting a burning coal into the thatch; the night being *so bright* that he could distinctly recognise his features at that distance. This occurred in the middle of December. Subsequently, a gentleman of undoubted veracity swore that he recollected the night of the attack, and that it was *so dark* that he could not see his horse's head as he rode along! On reference to the almanack, it was found that the moon was at the time in her last quarter.

The extraordinary resemblance which is occasionally observed between two individuals furnishes another ground for extreme caution in swearing to the identity of a prisoner not absolutely taken in ipso facto.

At the Old Bailey in 1822 Joseph Redman was indicted for assaulting and robbing Wm. Brown. The prosecutor, on his cross-examination, stated that he knew a man named Greenwood, who, with his hat on, so much resembled the prisoner that he should hardly know one from the other; Greenwood was in custody, and was brought to the bar, when the extreme similarity between the two men struck every one present with astonishment. Redman proved an alibi, and the jury returned a verdict of not guilty.

The case of the Perreaus was a remarkable illustration of this fact. Daniel and Robert Perreau were twin brothers, and in 1775 were tried and executed for a forgery on Mr. Adair. So great was the resemblance between them, that Mr. Watson, a money scrivener, who had drawn eight bonds by order of one or other of the brothers, hesitated to fix upon either; but being pressed to make a positive declaration, he at length fixed upon Daniel. The name of these unfortunate men is familiar to the public from the well-known exclamation of George III., when asked to pardon Dr. Dodd,—“If I save Dodd, I shall have murdered the Perreaus.”

A very remarkable instance of personal resemblance was for some years under our own observation in the sons of a poor peasant.

* From the *Causés Célèbres*.

They were twins, and so much alike, that one of them, who was very wild, used frequently to bribe his brother to change clothes with him, and go home to take a beating in his place; the father having no other means of distinguishing them except by their dress.

An individual was indicted and tried at New York in 1804 on a charge of bigamy, and the whole evidence turned on the question of his identity. He was called Thomas Hoag by the public prosecutor, but stated himself to be Joseph Parker. Several witnesses swore that he was Thomas Hoag, among whom was a female whom he had married and deserted. It was stated that Hoag had a scar on his forehead, a small mark on his neck, and that his speech was quick and lisping. All these peculiarities were found on the prisoner. Two witnesses deposed that Hoag had a scar under his foot, occasioned by his treading upon a drawing-knife, and that this scar was easy to be seen, and had been seen by them. On examining his feet in open court, *no scar was to be found on either of them*; and it was further proved, that at the time of his alleged courtship of the second wife in Westchester county, he was doing duty as a watchman in the city of New York. The jury acquitted him.*

3. We must not omit to mention the necessity that occasionally occurs for identifying the dead, as in cases of murder, accidental death, exhumed bodies, &c., cases which not unfrequently present themselves under very embarrassing circumstances.

In January 1817, the body of a woman was found tied to a boat near Greenwich Hospital, and an inquest was accordingly held, but adjourned on account of vague evidence. At the second sitting an old man declared the deceased to be his daughter, who had been the wife of an out-pensioner, and between whom and her husband a fight had taken place with sharp instruments in his presence; that soon afterwards both parties left his house, and he had not heard of them since. Other witnesses also supported the statement that it was the body of the old man's daughter. A second adjournment took place. The constables in the mean time had sought in vain for the husband, but *they found the wife alive*, and she was produced accordingly. The coroner reprimanded the witnesses, though the strong likeness between the living and the dead woman was allowed to be sufficient to impose on even better judges.†

In swearing to the identity of a dead person, witnesses should be very cautious how they assume any except indelible marks as means of recognition, because so complete an alteration takes place in the features and general appearance soon after death as to deceive even the nearest relatives. A trial took place some years ago in Edinburgh, which illustrates satisfactorily this part of our subject. A prosecution was instituted against four medical students for exhuming the body of a lady. The

body was so disfigured that it could not be identified by the friends; the ovaries were, however, examined, and it was reported that there was found in one of them a perfect corpus luteum, which would be sufficient to prove that the remains were not those of the lady in question, who was a virgin, and advanced in years. On the trial there was a total contradiction between the medical witnesses as to the corpus luteum, but the body was afterwards identified by a dentist who produced a cast of the gums which he had taken before death.

Even under circumstances apparently less difficult great doubt may exist as to identity. A resurrection man was lately tried before the high court of judicature in Edinburgh for raising the body of a young woman from the church-yard of Stirling. Nine weeks after death, the body was discovered and identified by all the relations, not only by the features, but by a mark which they believed could not be mistaken, she being lame of the left leg, which was shorter than the right. There was a good deal of curious swearing as to the length of time after death that the body could be recognised, but the jury was convinced that the *libel was proven*, and gave a verdict accordingly. "Now, I am certain," adds the relater* of this case, "that this was not the body of the woman who was taken from the church-yard of Stirling, but one that, at least six weeks after the time libelled, was buried in the church-yard of Falkirk, from which she was taken by this man, who also had taken the other, for which he was tried; she also was lame of the left leg: thus, though guilty of the offence laid to his charge, he was found guilty by a mistake of the *corpus delicti*."

4. From the foregoing cases may be collected a general view of the facts or circumstances likely to engage the attention of a witness, or a court, in cases where the identity of an individual may be doubted or disputed, and of the circumspection necessary in giving testimony on such a subject; in doing which we ought always to keep in view the following considerations, at least.

Seeing the great resemblance that may exist between different persons, we should hardly ever, after a lapse of any considerable time, trust to our mere recollection of external form or peculiarity of features, except we are able to connect these with some indelible or unalterable mark, such as *nævi*, *cicatrices* produced by disease or operations, congenital malformations; with reference to which object it would be very desirable that medical men practising midwifery should in all cases note down along with the other circumstances of time of birth, &c. any bodily peculiarity of the infant by which it might afterwards be recognized. We once detected by this means an attempt at substitution of a child, which would otherwise have certainly succeeded.

We should remember and make allowance

* Beck's Medical Jurisprudence, p. 223.

† Smith's Principles of Forensic Medicine, p. 500.

* See Beck's Elements of Medical Jurisprudence, p. 223, note, signed *Dunlop*.

for the great alteration that may be made in the person and countenance by the mere lapse of time, especially at the season of life when youth is matured into manhood, and by altered habits. When the brethren of Joseph stood before him, "they knew him not." If to time be added the effects of a hot or very cold climate, or disease, the pressure of mental anxiety or bodily hardship, the effects are still more striking :

Danger, long travel, want or woe
Soon change the form that best we know ;
For deadly fear can time outgo,
And blanch at once the hair :
Hard toil can roughen form and face,
And want can quench the eye's bright grace,
Nor does old age a wrinkle trace
More deeply than despair.*

The return of Ulysses, and his rejection from his own halls, unknown by all, and recognised by his faithful dog alone, although probably no more than a poet's fiction, has been realised in more instances than that of Casali.

In conclusion, it appears to us that in the case of a person seeking to establish a claim by proving his identity, a more certain mode of examination would be to question the person himself as to his knowledge of facts, however trifling in themselves, but of which he must have had cognizance if really the person he pretends.

(W. F. Montgomery.)

IMPETIGO, *humid or running tetter*,† (from *impeto*, to infest), is a non-contagious, pustular affection of the skin, terminating in thick lamellated scabs or thin scaly crusts. Willan and Bateman, who are followed by Bielt and Rayer, enumerate five species of impetigo; but in our opinion there are only two distinct species, the one unattended by febrile symptoms, the other preceded by them; the first three forms of impetigo may be ranked as varieties. We therefore propose the following arrangement :

Spec. 1. *Impetigo simplex*.

Var. a. *Impetigo figurata*.

b. *Impetigo sparsa*.

c. *Impetigo scabida*.

2. *Impetigo erysipelatodes*.

The first of these species (*impetigo simplex*) appears generally without any obvious premonitory symptoms, attacks chiefly the young, and those of a lymphatic temperament; and displays itself in clusters and groups of psudracious, or irregular, slightly elevated, small pustules, which, after discharging their contents, continue to exude a thin, acrid ichor, accompanied with much itching, or rather stinging, and a sensation of heat. This discharge concretes into thin, yellowish, semi-diaphanous scabs, which turn up at the edges, so as to allow the discharge to ooze from under them. The disease is frequently chronic, or

kept up by successive eruptions of the groups of pustules. The two first varieties of this species are founded on the manner in which these patches of eruption appear; whether large, circumscribed, oval, or some other regular figure; or small, disseminated, and assuming no peculiar form: the third variety is distinguished by forming one continuous crust over the affected part.

Impetigo figurata. This variety of simple impetigo generally occupies the face, appearing most frequently on the cheeks, the chin, the sides of the nose and margin of the nostrils: the extremities, particularly the hands, are often the seat of the eruption; it occasionally, also, appears upon the trunk of the body. Although, in general, this variety occurs without any obvious diseased state of the general habit, yet it occasionally follows much mental anxiety, or other depressing affections of the mind, in which case it is accompanied with cardialgia and uneasiness of the stomach, with a sensation of weariness of the limbs, and other indications of low febrile disturbance. At first the patches are small, distinct, red spots, which itch considerably: in a short time, however, they enlarge and are covered with minute yellow psudracious pustules, closely crowded so as to be almost confluent, and surrounded by a red inflamed border. The pustules are flat, and are the source of much heat and stinging pains. In a few days they burst, and discharge their contents; the pus drying and changing into thin semi-transparent crusts, which characterize this species of impetigo; sometimes, however, the scab is thicker and not unlike "the exudation of gum on a cherry-tree."* If these scabs fall or are rubbed off, the surface appears red, excoriated, shining as if stretched, and exhibiting minute pores from which an ichorous discharge exudes, which greatly augments the heat and smarting. On the margin of these diseased patches, unbroken psudracious pustules may be observed. When the disease is not perpetuated by successive eruptions, the crusts gradually dry, and remain nearly stationary for two or three weeks, the itching, heat, and smarting gradually diminishing; they then fall off, leaving the surface red, stretched and shining, and the cuticle so thin as to be liable to excoriation from the slightest friction. More frequently, however, the ichorous discharge is reproduced, accompanied with fresh crops of psudracious pustules; and the eruption is thus repeatedly renewed and runs its whole course; continuing for many months, sometimes for years. When the disease yields either spontaneously or to the influence of medicine, the amendment is first perceptible in the centre of the patches; and sometimes, even when this occurs, the border not only retains its diseased character, but fresh pustules shew themselves: as the cure proceeds, however, these also gradually disappear, and the whole skin acquires its natural

* Scott's Marmion.

† *Syn. Lepra squamosa* (auctor. var.); koubia (*Avicenna*); *ecpthisis impetigo* (*Good*); *phlysis impetigo* (*Young*); *dartre crustace* (*Fr.*); *der kleinausatz* (*German*); *cowrap* (*Javanese*); *herez* (*Arabic*).

* *Rayer, Traité Theorique et Pratique, tom. i. p. 474.*

aspect, except that it is covered with minute scales, which are reproduced for an indefinite time, more or less protracted according to the severity of the previous disease.

This variety of impetigo simplex does not always preserve the uniform course which has been described. Sometimes the patches enlarge by successive marginal crops; this is particularly the case when they appear on the legs, which are thus often gradually covered from above the knee to the instep. In some instances, the pustules are intermixed with transparent vesicles, not unlike those of some of the varieties of herpes; indeed there seems to be some affinity between the causes of herpes and impetigo; as the two diseases occasionally appear simultaneously upon the same individual. We have at present a case of severe herpes *zona* under treatment, in a man who has scarcely recovered from a protracted attack of impetigo *sparsa*. When these vesicles break, the ichor which they pour out is much more acrimonious than that of the pustules: wherever it touches the sound skin, inflammation and a crop of vesicles or psudracious pustules follows. The vesicles appear in tardy succession, and are slower in their progress than the psudracia: when broken, they are little disposed to heal; and the constant irritation of the ichor inflames the cuticle, thickens it, and covers it with small ulcers. In this state of the disease the burning sensation and itching are extremely distressing, and much increased by friction, or any source of irritation, or even any application, however emollient.

Impetigo *sparsa* differs from the former variety chiefly in the irregular and scattered distribution of the pustules: these appear in small groups, dispersed without any regular order in the extremities, about the neck and shoulders, and occasionally on the face, the ears, and scalp. They run the same course as those of impetigo *figurata*, but the scabs which succeed the bursting of the pustules are thicker, more friable, and do not form in so large plates as the former variety: the surrounding inflammation is, however, more extensive, and they oftener terminate in ulceration, interspersed with fissures,* and not unfrequently are accompanied with œdema.

Impetigo *scabida* of Willan and Bateman† is merely a more severe form of the last variety. It commonly appears on the legs; and the pustules are so numerous, and discharge so abundantly, that the greater part of the limb becomes incased in a yellow crust, variously divided by deep fissures, and not unlike the bark of a tree. When it extends over the joints, the movements of the limb become difficult and painful; and the heat, itching, and tingling are greater than in either of the former varieties. When any portion of this crust spontaneously separates, or when it is removed, the vacuity is quickly filled up by

the copious discharge poured out from the excoriated surface; the limb generally swells, and if the eruption extend to the toes, the nails drop off, and the new ones are thick, irregular in their form, and notched.

The causes of these varieties of the simple impetigo are very obscure. There seems to be a peculiar predisposition to the disease connected with the sanguine or the sanguineo-melancholic temperament, with a thin lax state of cuticle. We have already stated that impetigo *figurata* is sometimes preceded by gastric derangements, languor, and headach; and this is true of the other varieties; but more generally it cannot be traced to any derangement of the digestive function. In the predisposed, however, it has been observed to follow violent exercise, intemperance, or the use of tainted animal food; and, like some other cutaneous eruptions, it has been traced to mental agitation and to sudden causes of depression, such as disappointment, grief, and fear;* and occasionally to exposure to cold. The first variety in particular seems, also, to be connected with an irritable condition of the system, such as accompanies dentition in infants, and the appearance of the catamenia in women. The third variety does not appear to be influenced by the changes of season, but the first is liable to recur in the spring, and the second in the autumn, often continuing through the winter and disappearing in summer.

Some external irritants acting upon the skin produce pustular tetter closely resembling those of impetigo *sparsa*; in this way the eruptions termed grocer's and bricklayer's itch is produced; the former arising from the acrid stimulus of raw sugar, the latter from that of lime, acting on the hands and arms of those who are constantly handling these substances. In both cases the disease is readily distinguished from scabies; it is not contagious, and soon disappears when the sources of irritation are removed. Bateman regards the pustular eruption arising from the application of tartar emetic, and various stimulating plasters to the skin, as displaying some affinity to impetigo; but the pustules are of a very different character, distinct, elevated, and seated on a hard inflamed base, which is never the case in any of the varieties of this eruption.

Diagnosis.—The foregoing varieties of impetigo may be confounded with several other cutaneous affections, but attention to two or three of the most obvious characters common to all the varieties furnishes us with the means of forming a correct diagnosis. Thus the nature of the crusts distinguishes impetigo from eczema, which is, besides, a vesicular disease; and from porrigo larvalis and favosa. Impetigo *figurata* appearing on the face may be recognized also by the character of the crusts, which are thick, soft, and cellular in porrigo, and do not dis-

* See Atlas of Delineations of Cutaneous Eruptions, pl. xv.

† Practical Synopsis, 7th edit. p. 222.

* Med. Trans. vol. i. art. 2. Med. Obs. and Inq. vol. i. art. 19. Pract. Synopsis, 7th edit. p. 214. nota.

charge thin ichor, but thick glutinous pus. The hard inflamed base of the pustules of ecthyma prevents impetigo from being confounded with that eruption; and although, in its advanced stage, impetigo is frequently mistaken for lepra and psoriasis, yet the diagnosis is not obscure, if we discriminate between the scaly exfoliations of the latter and the laminated crusts of the former, or the ichorous discharge of the pustules of impetigo, and the complete absence of all fluid discharge in lepra and psoriasis. Between impetigo and scabies the diagnosis is not more difficult: the distribution of the eruption in patches; the copious discharge of ichor; the rough and fissured cuticle; and the heat and tingling which accompany the itching in impetigo, are sufficient guides for recognizing the disease. It is more likely to be mistaken for some of the syphilitic scabby eruptions, especially when these appear on the face. A case of this kind is mentioned as having occurred under M. Bielt, in the hospital of Saint Louis, and having been treated for some time as impetigo *figurata*; but the nature of the scabs, which are large, black, thick, very adherent, resting upon a violet-coloured base, and when separated, leaving deep ulcerations, with the regular, circular form of the eruption, are generally sufficient to distinguish this syphilitic eruption from impetigo.

Prognosis.—The only circumstance to be attended to in the prognosis of impetigo is the disposition which the eruption always shews to recur: it is more likely to prove obstinate in old people, and in weakened states of the system, than in the young and robust; but under no circumstances can it be regarded as a fatal disease.

Treatment.—The same treatment is applicable to all the varieties of simple impetigo. The internal administration of sulphur, either alone or combined with soda, nitre, and the bi-tartrate of potassa, is strongly recommended by Willan and Bateman in the commencement of the disease; but our experience leads us to agree with MM. Cazenave and Schedel, that the preparations of sulphur have been too indiscriminately employed, and that they have frequently proved hurtful, aggravating the symptoms, and favouring the disposition of the eruption to re-appear. The sedative and cooling influence of conium in the common effervescing mixture, with the aid of emollient fomentations, or even of simple tepid water, constitute the best and most efficient means in the incipient stage of any of the three varieties which have been described. In cases of impetigo *figurata* extending over a considerable portion of the skin, particularly when it attacks the face, M. Bielt recommends moderate bloodletting, either local or general; we have never ordered either, and indeed cannot exactly conceive how the abstraction of blood is likely to prove useful. When fever accompanies the eruption, we have found no difficulty in controuling it by antimonials and calomel.

If simple impetigo proves obstinate, an alterative course of mercurials, either hydrargy-

rum cum creta or Plummer's pill, with sarsaparilla or decoction of cinchona bark, is generally supposed to be indispensable; but we have found the occasional administration of five or six grains of calomel at bed-time, followed by a brisk cathartic next morning, and the arsenical solution given in the decoction of elm bark three times a day, more beneficial. In many habits, indeed, the skin is peculiarly sensitive to the stimulus of mercury, whether internally administered or applied to the surface; in these cases in particular, mercurial alteratives prove hurtful. Every description of local application has at one time or another been employed in impetigo; in some cases even the most soothing and emollient cannot be endured; in others the most stimulant have been applied with advantage. When the discharge is profuse, ointments prepared either with the oxide of zinc, or the white precipitate of mercury, or the subacetate of lead, have been found most useful in moderating the quantity of the discharge, and allaying the irritation. In a drier and less irritable state of the eruption, the ointment of the nitrate of mercury diluted with six or seven parts of lard or of simple ointment, or the tar ointment, will be found advantageous in securing a more healthy surface when the crusts separate. We have also seen an ointment formed by triturating two drachms of sub-nitrate of bismuth with an ounce of simple ointment very serviceable in this condition of the eruption. In the thickly encrusted state of the limbs, in impetigo *scabida*, no local application will prove beneficial until the incrustations are removed, which is best effected by poultices, or by exposing the limb to the vapour of hot water: after the crusts are removed, the surface should be covered with pledgets of lint, thickly covered with any of the mild ointments above mentioned, or touching the whole with a solution of nitrate of silver.

In many instances the irritation is scarcely supportable: in such cases we suggested, some years ago, the use of the hydrocyanic acid, in the proportion of half a fluid drachm to two fluid ounces of water, with half a drachm of alcohol, and two or three grains of acetate of lead, as a lotion which not only soothes the irritation, but disposes the skin to regain its healthy action: subsequent experience has sufficiently established the value of this application. It is proper, however, to mention that Mr. Plumbe met with two cases in which its application was followed by considerable intermission of the pulse, which ceased on discontinuing the use of the lotion; but in these cases both legs were affected, and the lotion was consequently most extensively applied, which may in some degree account for the effect it produced. We have never met with any unpleasant result, although we have most extensively employed this form of lotion.

In very obstinate chronic cases of impetigo, the baths of Harrowgate, or the artificial sulphur fumigating baths, generally prove effec-

tual, not only in clearing away the eruption, but likewise in preventing its return. With the same view the waters of Barèges, Enghien, Bonnes, and some other of the continental springs, and also the warm sea-water bath, followed by a course of sea-bathing, have proved highly beneficial. In every stage of the disease, the advantage to be anticipated from any plan of treatment depends much on the discrimination of the practitioner. In cases accompanied with much irritability of surface, the internal means should be of a sedative kind; and local applications, with the exception of tepid water, should be wholly abstained from, until some abatement of the irritability admits of the employment of the hydrocyanic acid lotion. In the opposite condition of the disease, the moderately stimulant ointments, with the internal employment of the arsenical solution, will be found the most effectual mode of treating these forms of this troublesome disease. Under all circumstances the diet of the patient should be milk and farinaceous matters, with a very moderate proportion of animal food once a day; wine, spirits, and every description of fermented liquor, must be sedulously avoided.

Impetigo *erysipelatodes*, the second species of this eruptive disease, closely resembles, in its commencement, the ordinary appearances of erysipelas, with slight febrile symptoms, which are followed by a puffy swelling of the upper part of the face, accompanied with redness and an oedematous state of the eyelids. The inflamed surface, on close examination and running the finger over it, appears papular, and in a day or two it becomes covered with psudracious pustules, that break and discharge a hot acrid fluid, which irritates and often excoriates the sound surface on which it flows. This state of the eruption, which often covers the greater part of the face, and extends to the neck and chest, is attended with the same heat, itching, and tingling, that accompanies the varieties of simple impetigo: it continues in this condition for some days, the discharge, as it diminishes, concreting and forming thin yellow scabs, in the interstices between which fresh pustules appear, and run the course already described. The disease continues for an uncertain period, sometimes for two or three months, and, in disappearing, it leaves the skin red, shining, and in the dry brittle state which follows the other varieties of impetigo.

This form of impetigo is liable to be confounded with eczema *impetiginodes* in the commencement, even by those acquainted with both diseases; in the advanced stage, however, the pustular form of the eruption sufficiently characterizes it. In some instances of the impetiginous eczema, a few psudracious pustules may be observed intermingled with its vesicles, but the latter greatly prevail.

Treatment.—The febrile symptoms which precede this eruption indicate the necessity of antiphlogistic measures in the commencement. Saline purgatives, with antimonials and nitre, generally alleviate the fever, after which decoction of cinchona bark, acidulated either with

muriatic or diluted sulphuric acid, may be administered with advantage. When the after stage of the disease proves particularly troublesome, and runs on for two or three months, a slight alterative course with sarsaparilla generally succeeds in completing the cure; or when it can be obtained, much benefit is derived from sea-bathing, or a course of Harrogate water. As local applications, nothing farther is required than tepid ablution, and guarding the excoriated surfaces with the ointment of oxide of zinc.

With respect to a supposed species of impetigo described by Willan and Bateman, under the title *impetigo rodens*, we have never seen the disease, and are rather disposed to regard it as a variety of malignant ulcer, complicated with psudracia.

(A. T. Thomson.)

IMPOTENCE.—*Impotence* or the incapacity of sexual intercourse, and *sterility* or the inability of procreation without loss of the power of copulation, are subjects which require to be considered, first as physiological questions, involving the consideration of all the causes temporary as well as permanent from which these defects may arise; and secondly, as a medico-legal subject, forming disqualifications for the matrimonial state, or affording pleas in exculpation of alleged rape or affiliation.

Impotence may exist either in the male or female; it is, however, most commonly found in the male, as from the nature and conformation of the genital organs in the female, physical impediments to coition more rarely occur, and she is generally enabled to admit the venereal congress at least in a passive manner. Sterility, on the other hand, is nearly confined to the female, for if the male be capable of accomplishing the act of coition, including of course the ejaculatio seminis, no farther question as to his virility can arise.

The causes of impotence may be divided into three classes: 1. organic; 2. functional; 3. moral.

In the human species, as in all the warm-blooded vertebrated animals, the procreation of the species is effected by a congress of the two sexes, and a variety of organs are provided, upon the integrity of which the due performance of this function mainly depends. The male is destined to furnish a peculiar fecundating secretion, which is to be deposited in the body of the female, and for this purpose he is furnished with glands which prepare this fluid, and also with a conduit by which it is conveyed to its proper destination; while the female, being the recipient, offers a cavity into which this secretion is received, and is, moreover, furnished with an organ where the embryo is originally produced by the specific action of the fluid from the male.

Without attempting to enter into an explanation of the process of generation, which has been rightly designated as "one of those mysteries which the present state of our knowledge does not enable us to explain or even to

comprehend,"* it may be admitted as the result of observation and experiment, that a failure in any part of this complicated apparatus is attended by impotence or sterility.

I. *Impotence in the male.*—In order to effect procreation he must possess all the organs of generation in a state capable of performing their respective functions, and this leads us to the first class of causes of impotence.

1. *Organic.*—Organic impotence may proceed from different sources; there may be, (a) deficiency of some of the organs of generation; (b) malformation of these organs; (c) diseases of some of them, or of the parts in their immediate neighbourhood, sufficient to impede the procreative function.

(a) *Deficiency of the penis, whether natural or accidental,* is an absolute cause of impotence. A congenital deficiency of this organ is very rare, but it has been observed. "J'ai traité et guéri," says Fodéré, "d'une incontinence d'urine un jeune soldat plein de courage et de vigueur, qui, avec des testicules bien conformés, n'avait à la place de la verge q'un bouton, comme un mamelon, par lequel se terminait l'uretre. Il m'assura avoir été toujours ainsi, et que ce bouton se renflait quelquefois en la présence des jeunes personnes du sexe, et qu'il en sortait par le frottement une humeur blanche."† Accidental deficiency of the penis is more common. This may arise from amputation or destruction by disease. In a subject lately procured for the purpose of dissection in the College of Surgeons, Dublin, the writer witnessed an instance of complete deficiency of the penis from operation. In this subject, which was a very old man, the amputation had been performed so long before death that the cicatrix was nearly obliterated, and many who saw the case supposed it to have been one of congenital deficiency.

It is difficult to determine the extent to which the penis may be mutilated without destruction of the power of procreation. The glans has been frequently lost without being attended by impotence, and both corpora cavernosa have been destroyed, but the urethra being preserved, the individual retained his virility.‡ Frank also states an instance of a gun-shot wound of the penis which carried away so much of the organ that it remained curved after cicatrization, nevertheless it served the purpose of procreation.§ From these and numerous similar instances, as well as from the effects produced on the generative function by that malformation, to be presently considered, termed *hypospadias*, it would appear that in order to insure impotence there must be complete deprivation of the penis, as a remnant capable of entering the vagina is sufficient for impregnation.

That the testicle is the only essential organ concerned in the secretion of semen is now

generally admitted, an opinion supported by comparative anatomy, as well as by the daily proofs we have in the castration of animals. A different opinion formerly prevailed, chiefly on the authority of Aristotle, who was led to deny the necessity for the existence of testicles from having seen a bull capable of impregnating a female after castration. But he was led into error by not being aware that if copulation were performed immediately after castration, the quantity of semen retained in the vesiculæ seminales would confer fertility on the coitus. The complete absence of the testicles then, whether natural or accidental, must render the individual unfruitful.

Congenital deficiency of the testicles is a very rare occurrence, if it ever takes place. Fodéré doubts that it does, and the case adduced by Cabrolomy of a soldier addicted to sexual pleasures in whose body no testicles were found, although the vesiculæ seminales were distended with semen, has been supposed by Portal to have been one of those instances in which the testicles are retained in the abdomen during the whole of life, and that they thus escaped observation. It is not to be inferred that an individual is impotent or sterile in whom no testicles are found in the scrotum. We know that in some instances these organs do not descend from the abdomen for some time after birth, and instances are not wanting in which this delay is prolonged through the whole period of existence. In order to distinguish if the absence of the testicles be real or not, it is necessary to enquire on the one hand into the previous history of the individual, and on the other into his present condition and general habit. The first may indicate the previous existence of these organs in the scrotum, and their removal by operation or accident, in which case the external marks of mutilation, such as cicatrices, will be apparent. We do not think, generally speaking, that an absolute congenital deficiency of testicles can take place without producing in the constitution the general phenomena by which the character of the male is obliterated, and that of the female simulated. In these cases of apparent absence of testicles, therefore, if the usual general signs of virility are observed, if masculine activity and vigour, combined with a well developed muscular system, a strong deep voice, with the usual covering of hair on the chin, breast, and pubis, and at the same time no cicatrix indicating castration, are present, we must be cautious in condemning the individual. However, it is necessary to be circumspect in inductions from the general habit. Marc knew a man in Paris whose features, thin beard, smallness of hands and feet, and voice altogether feminine, indicated a defect in genital organization, yet in whom none such existed; the testicles occupied their proper situation, and the man had many children.* Fodéré considered the retention of the testicles in the abdomen as a source of increased vigour and fecundating power. "Ces organes paraissant

tirer du bain chaud ou il se trouvent plongés, plus d'aptitude à la sécrétion, que lorsqu'ils sont descendus au dehors dans leurs enveloppes ordinaires."* This is at variance with the opinion of Hunter, whose views on the subject seem more correct, as he considers the delay in the descent of the testicles to arise from imperfection in their development. However, this imperfection does not go the length of rendering the organ useless, and therefore, when the other signs of virility are present, we are not justified in taking the absence of the testicles from their usual situation as an absolute proof of impotence. "Nous avons vu en France, dit Voltaire, trois frères de la plus grand naissance, dont l'un possédoit trois testicules, l'autre n'en avoit qu'un seul, et le troisième n'en avoit point d'apparens; ce dernier étoit le plus vigoureux des trois."†

Complete extirpation of the testicles, although it deprives the individual of the power of procreation, is yet not accompanied by total extinction of venereal desire, and it has been observed that eunuchs of this description retain the power of copulation in an imperfect manner. This is so well known in the East, that the eunuchs who have charge of the seraglios are deprived of the penis as well as of the testicles. This power in the castrato is alluded to by Juvenal,‡ and it is said that the unfortunate victims of avarice and bad taste in modern Italy are by no means deficient in capability of erection and penetration. However, this imperfect power of copulation does not remove such persons from the class of impotent, as the most important part of the function, the emissio seminis, is wanting. Monorchides, or persons with but one testicle, are not deprived of the power of procreation. This was at one time doubted, and in the year 1665 the parliament of Paris decided that such an imperfection rendered the matrimonial contract invalid. But numerous instances in man, as well as in the inferior animals, have completely disproved that opinion. It must be admitted, however, that if the remaining testicle be small, extenuated, and withered, and if a sufficient length of time has been passed in unfruitful matrimony, such a development must afford a strong probability of sterility.

(b) *Malformation.*—Impotence may be absolute when the genital organs exist, but are malformed or pathologically altered.

The penis varies from the natural formation in different ways that have been accounted causes of impotence. Mere diminutiveness of this organ, where the subject is otherwise vigorous, cannot be included under this head; and it would appear that the genital organs, although originally of diminutive size, are capable of considerable development even after the age of puberty. Of this the case related by Mr. Wilson is a good example. "I was," says he, "some years ago consulted by a gentleman on the point of marriage respecting

the propriety of his entering that state, as his penis and testicles very little exceeded in size those of a youth of eight years of age. He was then six-and-twenty; but never had felt the desire for sexual intercourse until he became acquainted with his intended wife; since that period he had experienced repeated erections, attended with nocturnal emissions; he married, became the father of a family, and these parts, which at six-and-twenty years of age were so much smaller than usual, at twenty-eight had increased nearly to the usual size of those of an adult man."* But excessive size, more particularly excess in length, may be considered as a relative cause of impotence, from the contusion and laceration inflicted on the female at each attempt at intercourse. Such cases as these are very rare. P. Zacchias cites an instance in which the female was always thrown into syncope from this cause.

The orifice of the urethra is occasionally formed in an irregular manner, and this constitutes the most common malformation of the penis. It sometimes opens in the perineum, sometimes on the dorsum of the penis, constituting the malformation termed *epispadias*; but most frequently in the under surface of the penis; this defect is called *hypospadias*. This malformation was considered by Mahon, P. Zacchias, Faselius, and Haller, as an absolute cause of sterility, but certainly without sufficient foundation; for there are numerous instances recorded in which impregnation has been effected by individuals in whom the urethra opened in an unusual manner, provided the orifice was in that portion of the penis that entered the vagina. Kopp relates the case of a peasant at Hanau, in whom the urethra opened on the under surface of the penis at the distance of eleven lines and a half from the extremity of the glans, notwithstanding which he was the father of five children.‡ Simeons of Offenbach gives eight cases of *hypospadias*. The first and second were married and had children; the first six, and the second four. The third and fourth were brothers; the fifth and sixth were sons of the first; the seventh was remarkable as having had an action for a divorce against him, and the eighth was an infant.† Foderé quotes four cases of *hypospadias*, in all of which the power of impregnating was preserved;§ and Belloc states that he knew at Agen a man who had the orifice of the urethra at the base of the frenum of the glans, and who left four children perfectly resembling himself, two of whom had the same malformation.|| From the cases on record in which impregnation has taken place without the possibility of intromission, it is clear that the emissio seminis in any portion of the vagina is sufficient for this purpose, and that it is not necessary that this fluid should be carried to the uterus, or to any great distance.

‡ 6th Satire.

within the vagina. We shall have occasion to revert to these cases in speaking of female impotence, but at present we mention them as affording an explanation of the subject before us. It may, therefore, be assumed that malposition of the orifice of the urethra does not necessarily constitute a cause of impotence, unless the opening be situated in a part that cannot enter the vagina. Even in the latter case impregnation may be effected by artificial means. The experiments of Spallanzani,* who succeeded in his attempt to impregnate animals by injecting semen into the uterus, led Mr. Hunter to adopt the same course in the case of a man by whom he was consulted in consequence of malformation of the urethra.† The orifice of the canal was in the perineum, through which the semen escaped during coition; and Mr. Hunter directed him to collect this fluid in a syringe and instantly to inject it into the vagina. The experiment succeeded, impregnation took place, and the female was delivered of a child in nine months.

A contracted state of the prepuce, by which the emission of the seminal fluid is impeded, may be a cause of impotence, but this is easily removed by operation. A more serious case is that in which the prepuce adheres to the glans, and the orifice of the urethra itself is contracted. The writer has at present under his care a boy, eleven years of age, in whom a malformation of this kind exists. The reflected portion of the prepuce adheres universally to the glans, and is firmly attached to the orifice of the urethra, which opening is so contracted as scarcely to permit the passage of an eye-probe. The urine is, of course, voided in drops. If this case be permitted to go on to puberty without relief, there is strong reason to imagine that impotence would be the result.

Malformation of the excretory ducts of the testicle may also prove a source of impotence. Mr. Hunter‡ represents a case in which the epididymis, instead of passing to a vas deferens, terminated in a cul-de-sac. A similar conformation sometimes occurs in the vesiculæ seminales, where, instead of entering the urethra, they terminate, after being joined by the vasa deferentia, in shut sacs. It is evident that when such a disposition of parts exists on both sides, the semen, although secreted, cannot be ejaculated, and, therefore, the individual is rendered absolutely impotent.

(c.) *Diseases.*—The diseases of the genital organs which cause impotence, may be divided into those affecting the penis, and those affecting the testicles. Of the former may be enumerated excess or defect of muscular or nervous energy, inducing priapism, or paralysis. Priapism gives rise to a temporary impotence when the erection is so vigorous as to close the urethra in such a manner that the semen cannot pass into it. Defect of energy in the vessels, nerves, or muscles of the genital organs, some-

times prevents the influx of blood to the corpora cavernosa in a quantity sufficient to cause erection, which produces a state of atony approaching to paralysis, constituting the anaphrodisia paralytica of Dr. Cullen. This is a disease not unfrequently met with. Instances of it are given by Chaptal, Gessner, Weicard, quoted by Foderé,* and also by Mahon,† in which it was removed by local stimulants.

Strictures in the urethra, when the canal is greatly diminished, may oppose such a barrier to the exit of the semen as to render the individual impotent; but it is extremely difficult to ascertain to what extent a stricture may exist without producing this effect. We know that many persons in whom strictures in this canal are found, do not lose the procreative power, and therefore, unless in extreme cases, where the finest bougies are with difficulty passed, we should be cautious in assuming this as a cause of impotence. The opening of the conjoined ducts of the vesiculæ seminales and vasa deferentia may be closed by scirrhus enlargement of the neck of the bladder, by enlargement of the prostate gland, a scirrhus state of the verumontanum, or by disease of the duct itself. Foderé alludes to the cases of two individuals mentioned in a French Journal,‡ who having full powers of copulation could never expel semen. On examination after death the seminal ducts of one were found filled with matter of stony hardness; and in the other the extremity of these ducts was callous and blocked up. All these causes produce inability for procreation by obstructing the passage of the semen, although this fluid be duly secreted.

But the cause of impotence may lie in the secreting organ itself, the texture of which is so altered by disease as to interrupt the performance of its natural function. Thus scirrhus, cancer, scrofula, when they affect the entire substance of the testicle, produce such an obliteration of its intimate structure that the seminal fluid is no longer formed. The form of disease described by Andral must be considered as belonging to this class: "Un état d'induration grise ou blanche du parenchyme avec disparition des conduits séminifères; le testicule représente alors une masse homogène, dure, où l'on ne trouve plus aucune trace de son organisation primitive."§ But in order to constitute complete impotence, it is necessary that both testicles should be implicated, and that the disease pervade the entire organ; for a small portion of the gland remaining uninjured may be still capable of secreting semen in a quantity sufficient for impregnation. "In the first method adopted in the East for making eunuchs, we are informed that the masculine efficiency was destroyed by bruising the testes, (a method of castration still pursued in some places with regard to animals,) and destroying their functionary powers along with

their organization. Instances of generating, however, seem to have occurred among eunuchs made in this manner, and are explained on the supposition that part of the testes remaining uninjured was still capable of preparing the necessary secretion, and furnishing it to a certain extent.*

Local injury may be followed by atrophy of the testicle, and it is well known that a state of complete inaction, such as is observed in those who have maintained a strict monastic life, is often attended by a similar result. Elephantiasis is said to cause a wasting of the genitals and a loss of all sexual appetite, but this is denied by other authorities. (See ELEPHANTIASIS.) A species of idiopathic atrophy of the testicles is described by Baron Larrey, which affected many of the French troops on their return from Egypt. In these cases the organs became soft to the touch, and gradually diminished in size without any pain. Foderé mentions that he observed in some young deserters condemned to work at the canal of Arles, that the testicles melted away just as if they had never existed.†

Diseases of the neighbouring parts may also prove a source of impotence by affording obstacles to the venereal congress. These are extraordinary obesity and very large scrotal hernia and hydrocele. Obesity, when extreme, must be considered a disease; of this, Martin, king of Aragon, furnishes a striking example. "He is stated by historians to have been so corpulent that neither mechanical contrivances nor medical treatment could render him any assistance towards the accomplishment of venereal congress."‡ Large scrotal hernia and hydrocele, by distention of the integuments, cause recession of the penis, and render coition impracticable. Besides, these tumours are considered by Foderé to impede the secretion of semen either by causing too great tension of the spermatic vessels, or by so compressing them that their diameter is obliterated. This effect, however, must be of rare occurrence.

2. *Functional*.—One of the most remarkable changes that take place in the transition from youth to manhood is the development of the sexual organs, and the new train of sensations by which it is accompanied. Puberty is the season of life in which the generative function is called into active operation, and unless impaired by excesses or disease, it usually continues in vigour until the sixty-fifth year. "The genital organs, says M. Virey, offer two states during life, in the young and old, which are the frozen zones of existence; the intermediate state is the torrid zone of life. The infant has nothing to give, the old has lost all."§ This doctrine, however, must not be received without limitation; for instances of precocity, as well as of protracted generating power, are not wanting. Dr. Ryan|| cites some examples

of children precociously developed, even before the fourth year; and he alludes to a case of a boy described by M. Virey, who at seven years of age was as fully developed as an adult, and who made the most furious attacks on his female acquaintance, and absolutely deprived one of them of that which she could never regain. Instances of vigorous senectitude are also occasionally met with. Of these the case of the celebrated Thomas Parr is, perhaps, the most striking. He married at the age of one hundred and twenty, and was compelled to do penance for an amour in his hundred and fiftieth year. But looking on these as exceptions to the general rule, it may be said that extreme youth or old age are incompatible with the exercise of the generative function.

There are, moreover, certain states of the body in which, although the genital organs be perfect, impotence may nevertheless exist, in consequence of incapability of erection. This may arise from constitutional frigidity, or what may be termed the apathetic temperament. The offspring of infirm aged persons, of parents too young, or of those worn down by debauchery, often present examples of this condition. The appearance of persons of this temperament is thus described by a French writer:* "The hair is white, fair, and thin, no beard, countenance pale, flesh soft and without hair, voice clear, sharp, and piercing, the eyes sorrowful and dull, the form round, shoulders strait, perspiration acid, testicles small, withered, pendulous, and soft; the spermatic cords small, the scrotum flaccid, the gland of the testicles insensible, no capillary growth on the pubis, a moral apathy, pusillanimity, and fear on the least occasion." Impotence arising from this cause is usually incurable.

A more common source of impotence is a particular weakness of the generative organs arising from too early coition, from abuse of venereal pleasures, or from indulgence in the pernicious crime of masturbation. In persons whose organs are debilitated by these causes, erection does not take place, although the mind be highly excited by lascivious ideas. The erector muscles have lost power from over use, and are to a certain extent paralysed; and if semen escapes, it is clear, serous, without consistence, and consequently deprived of prolific virtue.

Among the causes of general debility capable of producing impotence, have been reckoned defect of nourishment, bad quality of food, and unwholesome regimen. But we would observe that these influences must be exerted to the very extreme before they can produce the effect described, for in this city (Dublin), where misery, poverty, and starvation exist to a degree perhaps unparalleled on the face of the globe, procreation proceeds with extraordinary rapidity; and it has fallen to the writer's lot, through his connexion with the Coombe Lying-in Hospital, to witness the birth of numberless infants whose unfortunate parents had not for years partaken of a wholesome meal.

|| *Loc. cit.*

* *Dict. des Sciences Méd. art. Impuissance.*

The habitual abuse of spirituous liquors, long watching, excessive evacuations of blood, bile, saliva, or fæces, as they tend materially to depress the powers of the constitution, may prove temporary causes of impotence. To this class Marc* adds the sedative action of opium, hyoscyamus, and tobacco. The influence of the narcotic gases, in consequence of the sedative effects they produce on the sensitive system, sometimes gives rise to a temporary impotence. Of this the following case given by Foderé is a good example. "J'ai traité un homme âgé d'environ quarante ans, qui, ayant échappé à un état apoplectique occasioné par la vapeur du charbon, reste tellement impuissant pendant six mois, qu'il étoit absolument insensible à toutes les caresses que sa femme, qu'il aimoit jusqu'à la jalousie, mettoit en usage pour l'exciter. Il reprit complètement ensuite son état naturel."† Certain substances, as the *nymphæa* or water-lily, nitre, camphor, colchicum, and indeed most of the diuretics, have been supposed to exert directly sedative effects on the generative organs. That this specific action can cause impotence is probably too much to assert, although some writers have done so; but from the beneficial effects we have obtained from the use of nitre and camphor in cases of over-excitement of the generative apparatus, attended with nocturnal emissions, it would appear that these substances are possessed of properties that tend to moderate the venereal appetite. We have heard of a patient rebelling against the continuance of the use of colchicum, in consequence of its impairing his virility. Dr. Paris takes notice of a peculiar species of impotence arising from debility which deserves notice. "It depends," says he, "upon a want of consent between the immediate and secondary organs of generation; thus the penis acts without the testicles, and becomes erected when there is no semen to be evacuated; while the testicles secrete too quickly, and an evacuation takes place without any erection of the penis."‡

We have already alluded to the effects of strict chastity on the testicles. In this state of decay impotence is the final result. There are some diseases which stimulate the generative organs, such as gout, rheumatism, hemorrhoids, calculus in the bladder or kidneys: in the latter disease the constant irritation propagated to the glans penis frequently urges the sufferer to coition even during the most severe pain. But there are others which extinguish venereal desire during their continuance. These are nervous and malignant fevers, which engage the sensorium from their commencement, and are accompanied with general weakness and prostration of excitability; and diseases of the brain and spinal chord, occasioned either by internal or external causes. Hennen§ mentions a case of a soldier who was rendered im-

potent by a blow on the occiput. With reference to the effect of diseases on the generative function, Foderé mentions a circumstance worth being remembered, which is, that it is possible that certain diseases may produce such an alteration in the constitution, that an impotent man may find himself cured of his impotency on their cessation. He adduces the instance of Avenyoes, who stated he had been without offspring during the whole of his youth, but became a father on recovering from a severe fever. Zacchias states a similar instance. An artisan lived twenty-four years with his wife without having children, when he was attacked by an acute disease, from which he recovered; the fruit of his convalescence was the birth of a son, after which he had many children. It is well known that persons recovering from acute diseases are often extremely salacious. Dr. Dunlop* gives an instance of this on the authority of a friend who visited the hospitals in New York, and who stated that patients recovering after the yellow fever exhibited most furious sexual passion, to the great inconvenience of the nurses and their assistants.

3. *Moral.*—We have already treated of those causes which produce permanent impotence, and of those disturbances of the constitution which during their continuance suspend the generative function: we have now to observe upon those causes which in a sound constitution, with perfect genital organs, are capable of suspending their action, but the cessation of which leaves them free to fulfil their office. These are strong mental emotions, such as too ardent desire, fear of not being loved or of being incapable, shame, timidity, surprise, jealousy, hatred, disgust, in short any thing by which the mind is forcibly arrested. A temporary impotence from this class of causes is by no means a rare occurrence. Of all the causes just mentioned, the fear of incompetence is most frequently productive of impotence. It was a knowledge of this fact that led Hunter to adopt the remarkable mode of treatment which proved so successful in a case of impotence. He prevailed on the person to promise on his honour to pass six nights in bed with a young woman without attempting sexual intercourse, and before the allotted time had expired, the patient's only fear was lest the force of desire should induce him to break his promise. Similar instances have occurred to most medical men, and have been cured by the same means. The facility with which the most vigorous man is rendered impotent by this cause, led to the supposition that supernatural agents were concerned in effecting it, and the natural credulity of mankind soon confirmed the idea. This belief in the powers of enchantment, or, as the French term it, "nouer l'aiguillette," has prevailed in most ages and countries. We have accounts of it in the East, in Egypt, among the Greeks and Romans; and even some of the early fathers of the church, St. Jerome and St. Augustin, are

* Dict. des Sciences Méd. art. *Impuissance*.

† Méd. Lég. tom. i. p. 382.

‡ Med. Jur. vol. i. p. 208.

§ Military Surgery.

* Beck's Med. Jur. by Dunlop.

said to have been imbued with it. Like other forms of enchantment, persons were found who made it their business to practise it, and even princes were subject to their dominion. Nero and Amasis were, at the suggestion of their concubines, rendered impotent by incantation. In this process there was always something to arrest the imagination; some drug was administered, some obscure and unintelligible words were pronounced, or written on paper with blood, and tied about the victim's neck; a lock of his hair was tied, with certain mysterious ceremonies, or some other equally absurd practice pursued, no matter what, so that the proper impression was made upon the mind, and as long as this continued, it had the power of preventing erection by the very fear of failure. The progress of knowledge has done for this species of witchcraft what it has for others, and it is now confined to the lowest and most ignorant people.

II. *Impotence and sterility in the female.*—

It is necessary to distinguish between these two conditions in the female, as it is quite possible for a woman to be impotent and not sterile, and sterile but not impotent; in other words, there may exist a malformation of the genital organs of such a nature as to prevent intercourse, on the removal of which she becomes fruitful; and, on the other hand, she may be perfectly competent to copulation, yet never conceive. The latter is by much the most common, and is believed to occur more frequently in the female than impotence does in the male. Strictly speaking, impotence can only be said to exist in the female when the vagina is incapable of admitting the penis. By this incapacity, however, sterility is not always insured, as it will appear from cases to be presently alluded to, that impregnation has taken place when intromission was impossible. But laying aside these instances, as exceptions, it may be stated generally that an impervious vagina is attended with impotence. Such a condition of the female organs may be the result of various causes existing either in the hard or soft parts. It is rare to find the impediment originating in the former, but Foderé alludes to a malformation of the pelvis, such as considerable depression of the pubis, or exostosis, as capable of opposing the act of generation: we cannot, however, believe that deformity of the pelvis caused by approximation of the pubis and sacrum can offer such a barrier as he supposes; and we are strengthened in our disbelief by the many instances recorded, in which impregnation took place notwithstanding the highest degree of deformity. But an exostosis, when it attains a great magnitude, may very well prove an obstacle to coition. The cause of impotence is more frequently found in the soft parts, and this may be either absence or occlusion of the vagina. Cases in which the vagina was altogether wanting are not numerous, but there are some recorded, and of these one of the most remarkable is detailed in the *Causes Célèbres*.* We will not

give the case at length, but the leading facts were the following. A young woman in Paris was married in her twenty-fifth year to a young man named La Hure. Six years were passed without consummation of the marriage; and then the woman was examined by a midwife, who declared all the external organs of generation wanting, and their place occupied by a solid body pierced by a small hole. The woman admitted that she had never menstruated; nevertheless she had always enjoyed good health. A surgeon, named Dejours, who saw the case at this time, supposing it one of simple occlusion of the vagina, proposed to divide the barrier, in hopes of reaching and laying open the cavity. He accordingly carried a scalpel to the depth of two fingers' breadth, but instead of reaching a vagina, he was still opposed by solid resisting parts. Finding this, he judged that he had nothing to hope for in going further, and that he should run great risk of wounding the bladder or rectum. He therefore endeavoured to keep open the wound he had made by the introduction of tents, and this opening remained during life. Matters continued quiet for eight years more, when the husband, disgusted with his wife, demanded a divorce. The woman died at Lyons ten years afterwards, and on examination it was found that the place of the vagina and uterus was occupied by a hard compact substance, in which no cavity could be traced. Not long ago a case somewhat similar was exhibited to the Society of the Faculty in Paris, in which no uterus or vagina existed, and the perineum was pierced by a small hole, which was the termination of the urethra.

A more common case is that in which the calibre of the vagina is so diminished as to resist the intromission of the penis. Several instances of this malformation are to be found in writers on legal medicine and midwifery, one of which we may mention, as it affords a striking example of the manner in which nature accommodates parts to the offices they are called on to perform. A young girl, married at the age of sixteen, had the vagina so narrow, that a goose-quill could scarcely enter it. A young and vigorous husband had failed in all his attempts, and some of the faculty who were consulted declared copulation impracticable. Nevertheless, after eleven years this woman became pregnant without any increase in the dimensions of the vagina. Her friends of course despaired of the possibility of delivery; but about the fifth month of pregnancy the vagina began to dilate, and at the full time it had acquired a size sufficient to permit the passage of the infant.* In the celebrated Joan of Arc, the Maid of Orleans, according to the account of two physicians who were ordered to examine her, the vagina was found so contracted that coition must have been impracticable. Malformation of this kind is frequently removable by appropriate treatment. In a case that occurred to Benevoli, he employed emollient fomentations and tents, and

* Tom. vii. and x., *Vingtième cause*.

* *Mém. de l'Acad. des Sciences de Paris*. 1712.

by gradually increasing the size of the latter, succeeded in removing the imperfection.

In those cases in which the uterus is divided longitudinally into two chambers, it sometimes happens that the septum is prolonged into the vagina, even to the vulva.* In this condition of parts, if the intervening membrane be firm and rigid, it may oppose a barrier to coition. The vagina may be also too short and terminate abruptly in a cul de sac; this disposition of parts may be congenital, but it may be also the result of difficult labour. When congenital, it is usually attended by absence of the uterus.

The inflammation that sometimes follows difficult labours (particularly if instruments have been incautiously used) has been known to cause adhesion of the sides of the vagina, and so cut off all communication with the uterus. The writer is acquainted with a very remarkable instance of this accident at present in the Coombe Lying-in Hospital, Dublin. The sufferer is a young healthy woman, in whom there is a fistulous opening between the bladder and vagina, and just beyond the opening the sides of the vagina adhere firmly. She applied at the hospital in hopes of obtaining some relief from her miserable state, which she said was the consequence of a tedious labour, during which instruments of some sort were employed. It is remarkable in this case, that although the outlet for the menstrual discharge is closed, there is no indication that it is poured out by the uterus, for none of the signs of confined menses are present. We are therefore inclined to suppose that the cavity of the uterus itself has been obliterated by the inflammation, and consequently that an operation would not be attended with success.

The vagina is frequently found closed at its orifice: this may be caused in different ways. It is sometimes produced by neglected inflammation and excoriation of the labia in children, and even in adults; and this has extended in some cases to a complete closure of the canal, so that no passage has remained but a small one at the superior anterior part for the discharge of urine. Dr. Ryan† states that he has seen four cases of cohesion of the labia externa at the age of puberty, so complete that only a small probe could be introduced at the superior commissure. Dr. Meriman once met with an instance where the entire opening of the labia was so perfectly closed, in an infant of two years old, that there was not the smallest aperture through which the urine could escape.‡ We find in the works of Ambrose Paré, Ruysch, Fabricius Hildanus, Benevoli, and others, examples of complete obstruction of the vagina, either at its orifice or at a greater or less depth, by a membrane of such strength as to resist intromission. Dr. Meriman§ relates the case of a young woman whom he was called to at-

tend in her first accouchement, and on proceeding to make an examination he found it impossible to introduce his finger into the vagina, that passage being closed by a membranous expansion about one-tenth of an inch in thickness. This membrane occupied the entire opening of the vagina, with the exception of a small aperture through which a pea could hardly have passed. It was finally ruptured by the child's head, and delivery was safely accomplished. The same author gives another case related by Dr. Tucker, in which the obstruction was even more complete. "The labia pudendi were observed to have the usual situation and appearance; but being expanded, they were discovered to be connected to each other by a strong opaque membrane, nearly a finger's breadth, not distinguishable from their external skin in texture and appearance, which was stretched from the surface of the perineum (of whose outward skin it seemed likewise a continuation or production) over the longitudinal sulcus between the labia, and over the clitoris, quite to the pubis. About the middle of this membrane there was a circular aperture, with a strong ring, just large enough to admit a female catheter one-eighth of an inch in diameter." In this case the membrane was so strong that it resisted the forcible impulse of the child's head during several pains, and was at last divided artificially from the aperture to the frenum labiorum. These and many similar instances on record are the cases to which we referred in speaking of hypospadias, as confirmatory of the doctrine laid down there, viz., that an emissio seminis at the orifice of the vagina is sufficient for impregnation, and they afford instances of what may be considered paradoxical, that is, of women being impotent, yet conceiving. The following case from Foderé is so striking that we cannot omit to mention it. A young man had married a young woman, with whom, although he had frequently made the attempt, he could never consummate the marriage, "*à son gré.*" At the end of three months he demanded a divorce, although she declared herself pregnant. She was now examined by many skilful surgeons, who found a hard callous membrane placed at the mouth of the vagina; this they divided, and the operation succeeded so well that the husband relinquished his claim for divorce. The woman was delivered, in six months after the operation, of a male infant at the full term, and of great vigour. From these cases it is plain that this hypertrophied state of the hymen, although it affords a barrier to copulation, is yet capable of removal by operation, and therefore it cannot be considered as a permanent cause of impotence.

Narrowness of the mouth of the vagina is sometimes accompanied with a communication between that canal and the bladder or rectum. Foderé states two cases of this description, in both of which sterility prevailed. Procidencia of the uterus might be supposed to create impotence, were it not that some very remark-

* Andral.

† Manual of Med. Jurisprudence, p. 129.

‡ On Difficult Parturition, 3d edit., p. 221.

§ Loc. cit., p. 216.

able instances of the contrary are recorded. In the fourth volume of the London Medical and Surgical Journal, may be found a description of two cases of this disease, in both of which impregnation took place, although the natural orifice had been fixed without the vulva for years.

We now come to speak of sterility, or of those cases in which, the vagina being pervious, impregnation does not occur. This may depend upon imperfect development or total absence of the uterus, obliteration of its openings, diseases of this organ, obstruction or disease of the fallopian tubes, and absence or disease of the ovaria. That form of imperfection in the uterus in which one-half of the organ is wanting, and which case is attended with but one ovarium and one fallopian tube, does not entail sterility. Chaussier relates a case of this kind in which several children were born at the full time.* But there is a variety sometimes found which must render the woman barren; in which the uterus is so small that it is with difficulty found in the pelvis, and the fallopian tubes appear to terminate in the extremity of the vagina. We have already said that unnatural shortness of the vagina is frequently connected with absence of the uterus. Columbus dissected a woman who had always complained of great pain in coitu, in whom he found the vagina very short, and no uterus at its termination. A similar case occurred to Dupuytren: † the vagina was only one inch in length, the ovaria and fallopian tubes were well developed, but no uterus existed. Foderé states that this malformation may be discovered during life by the smallness of the breasts, &c.; but in the case mentioned by Dupuytren the breasts were well formed, the external genitals developed, and the whole appearance was feminine. It is plain that sterility must attend this defect.

The different orifices of the uterus may be obliterated, and thus impregnation will be prevented. The opening of the fallopian tubes has been found closed; and this may be owing to a simple continuation of the lining membrane of the uterus over it, or to the existence of a particular membrane blocking up the mouth of these tubes, or to an obliteration of the tube itself, which sometimes extends to the distance of some lines from the uterus. When both tubes are thus circumstanced, no uterogestation can go forward, for obvious reasons. But the mouth of the uterus itself is occasionally obstructed either by an adventitious membrane stretched across, or by an agglutination of its sides; and when this is the case, sterility is the result.

Besides the closing of the uterine extremity of the fallopian tubes, these canals are sometimes impervious throughout their whole extent; sometimes the obstruction is situated about the middle, and at others the fimbriated extremities alone are blocked up; and this

latter is frequently caused by an intimate adhesion between them and the ovaria.*

The ovaria are sometimes wanting. This deficiency may exist at but one side, a specimen of which is preserved in Dr. Hunter's museum; and Dr. Baillie takes notice of others in which these organs were deficient on both sides. Dr. Denman says he was shewn two preparations by Dr. R. Hooper, in which the fallopian tubes terminated bluntly, and without any aperture, fimbriae, or ovaria.†

Besides these impediments to impregnation, there are certain diseases of the female genital organs, which, when they exist, are found to cause sterility. Polypus in utero is very generally considered to belong to this class; but although the opinion is generally correct, it is not universally true, for it has happened that conception took place notwithstanding the presence of a very large tumour in the uterus. Of this the late Dr. Beatty‡ has described a very remarkable instance, which occurred in Dublin in the year 1820. The patient was a lady twenty-five years old, who, in consequence of the indisposition of her husband, had left his bed in May 1819, to which she did not return until August 1820. In the previous May she first perceived what she termed a "lump in her womb," attended with external swelling and soreness on pressure at the lower part of the abdomen. This swelling was not permanent, but was observed to disappear during the menstrual period. Finding an increase in her unpleasant symptoms, she applied to Dr. Beatty in September, and on the 28th of that month he made an examination per vaginam. The os uteri was found dilated to the size of a dollar, and in its opening was a large dense substance with a regular smooth surface. On the 10th of November, while out in her carriage, she had a moderate discharge of blood from the vagina, and upon examination the parts were found as they were a month before. At two o'clock the following morning she miscarried, the embryo was entire, the membranes not being ruptured: the contained fœtus was about three months' old—a period corresponding with the time at which connubial intercourse had been resumed, and at which she had last menstruated; and just three months after she first experienced uterine uneasiness. The tumour was expelled in six days afterwards by pains resembling labour, the uterus was inverted by its descent, but on separation of the slight attachment between it and the tumour it was easily reduced. The weight of the tumour was found to be nearly four pounds. This lady was delivered of a healthy boy on the 10th of February, 1822. This was an instance of pregnancy occurring during the existence of a tumour of considerable magnitude in the uterus; but we believe it to be an exception to what usually takes place.

Inflammation, suppuration, calculous depo-

* Morgagni. Baillie. Richerand. Andral.

sitions, cancer, cauliflower excrescence, corroding ulcer, the irritable uterus of Dr. Gooch, and any disease in which the texture of the uterus is much engaged, or with which the constitution sympathizes strongly, are so many obstacles to impregnation, as are diseases of the ovaria, in which the natural structure of these organs is obliterated, and both of them engaged. Leucorrhœa, when profuse, is very often also attended by barrenness; but this is by no means a constant effect, as we have known instances in which this disease existed to a great extent without preventing impregnation.

A question has arisen whether menstruation is necessary in order that a woman shall be prolific; and it generally stated that women who do not menstruate cannot conceive.* This is true when applied to those who have never menstruated, but is not in cases that have had even a single monthly discharge. Foderé† states that, in the first edition of his work, he had maintained that females who do not menstruate are sterile; but he afterwards was obliged to change his opinion, from having observed some patients under his own care enjoying good health without this evacuation, and bearing many children. One of them was a woman thirty-five years old, the mother of five children, the last of which she was suckling. She was in good robust health, and had never menstruated but once at the age of seventeen years. It would appear that a single occurrence of this periodical evacuation is a sufficient indication of generative power; and although irregularity in subsequent years is frequently attended by sterility, it is not to be taken as an absolute cause of it. There is a form of dysmenorrhœa described by Dr. Denman‡ and Dr. Dewees§ of Philadelphia, which both these authors state to be productive of barrenness. The striking peculiarity in this disease is the formation of an adventitious membrane in the uterus, which is expelled after severe and protracted suffering at each menstrual period. This membrane is sometimes thrown off in pieces, and at others entire, at which time it bears the strongest resemblance to the decidua, so much so that, when it occurs in unmarried females, it may and sometimes does give rise to most painful suspicions. There is a preparation in the museum of the College of Surgeons, Dublin, of an entire membrane of this kind, which might deceive the most experienced eye. Morgagni relates a very remarkable instance in which pregnancy occurred during the existence of the habit just described, but it is probable that there was a suspension of the disease for a time in that case, when the capability of conceiving might exist.

It is well known that instances have happened in which persons have lived for years in unfruitful matrimony, and being after divorce remarried, have both had children. This is a fact which in the present state of our knowledge

we are not able satisfactorily to explain, and we will not delay the reader by offering any speculative opinion upon it.

Treatment.—The treatment of impotence and sterility must be influenced by the causes from which they spring, some of which are incurable, whilst others may be removed by appropriate remedies. Those cases which depend upon congenital deficiency of the penis, testicles, vagina, uterus, fallopian tubes, or ovaria, belong to the former; but we have seen that some of those arising from malformation and disease of these parts are susceptible of cure. Such are phymosis, adhesion of the prepuce to the glans with diminution of the orifice of the urethra, priapism, partial paralysis, strictures in the urethra, diseases of the neighbouring parts, contracted vagina, occlusion of the mouth of this canal by adhesion of the labia, or by a dense hymen, prolapsus and procidentia uteri, polypus in utero, leucorrhœa, dysmenorrhœa: all these are more or less capable of removal either by operation or general treatment. The cases of impotence which depend upon functional or moral causes are much more numerous than those just mentioned, and frequently become the subjects of medical treatment. If old age be the cause, there is little to be done; medicines are useless, and temporary stimulants are often worse. There have been instances of old debauchees, who, wishing to make a last attempt, have taken some of the nostrums, such as the Venetian pastilles, Italian lozenges, &c. and have perished without success in the very effort. Cases arising from debility of the generative organs, from too early coition or the abuse of venereal pleasures, are not unfrequently met with, and indeed furnish the great mass of dupes to quackery. In the treatment of such cases there are many points that must be strictly attended to. We must be careful to remove from the imagination, or regimen, all that may excite the generative apparatus, while we endeavour to strengthen the system by mild nourishing diet and gentle tonics. We must combat on the one hand muscular weakness, and on the other nervous susceptibility, and so restore the equilibrium between the two systems. The local application of cold water has a great effect in allaying the excitable state of the generative organs, and should be had recourse to at least twice a day. If the impotence be owing to moral or physical irritation, the constitution must be lowered by spare diet, cooling acidulated drinks, exercise in the open air, and removal from all objects which excite venereal desires. This plan of treatment we think preferable to the employment of narcotics, which sometimes produce unpleasant effects, and are always hurtful to the digestive organs. In those cases which are purely the effect of atony of the generative organs, and do not arise from their over-excitement, a different line of conduct must be pursued. The diet should be full and generous, with a liberal allowance of spices and wine; and the exclusion of all objects of a nature to excite the senses need not here to be recommended. Frictions to the

§ *Dewees' Midwifery*, p. 154.

loins, and the cold bath, will be found useful; sometimes it will be necessary to substitute the warm bath when the cold does not produce the healthy reaction we desire. (See BATHING.) If these means fail, we may then have recourse to stimulating applications to the loins, thighs, and pubis, and electricity may be used with advantage. (See ELECTRICITY.) In the year 1776 Dr. Graham opened an establishment in London, in which were a number of electrical beds, destined to awaken the dormant generative powers in cases such as we have described.

Modern systematic writers have discarded that class of medicines formerly grouped together under the name of aphrodisiacs, from their supposed power of exciting a desire for venery: it consisted of stomachics, aromatics, odoriferous gums, balsams, resins, essential and volatile oils, perfumes, particularly musk, phosphorus, opium and aromatics combined, and cantharides. These, with the exception perhaps of cantharides, seem to act only as general stimulants, and do not possess any specific powers over the organs of generation. Cantharides, as is well known, when administered in large doses, are sometimes capable of inducing a violent state of irritation of the urinary and genital organs, indicated by strangury, bloody urine, priapism, &c.; but this condition can never be induced without other violent constitutional symptoms being also brought on, to the great hazard of life;* and we are much inclined to doubt that a person labouring under these effects is disposed to venereal enjoyments. However, cantharides have been for a long time employed as an aphrodisiac, and for this purpose they entered into the composition of many secret remedies, such as the Venetian pastilles, Italian lozenges, love potions of Italy and Turkey, &c. to the use of which we believe many have fallen victims. The "remède de magnanimité" of Kœmpfer, so called after its inventor, is composed of opium, musk, and ambergris, and is extensively employed in the East, where it is taken daily by the great for the purpose of exciting venereal desires.

From what has been said in commenting upon the different causes of impotence, it is unnecessary to prolong this article by any further notice of their medico-legal application; we will therefore conclude by deducing, in the words of Dr. Ryan, from the preceding statements, the following general principles:—

"1. To declare either sex impotent, it is necessary that certain physical causes be permanent, malformations or accidental lesions, and be evident to our senses, which art cannot remedy, and which prevent the faculty of exercising a fecundating coition.

"2. These causes, when rigorously examined, are few in number.

"3. The moral causes of impotence ought not to be taken into consideration, as they would serve for an excuse for an individual accused of impotence."†

(Thomas Edward Beatty.)

INCONTINENCE OF URINE. ENURESIS.

RESIS, from *ἐνυγγία*.

History of the disease.—In man the excrementitious secretions, although taking place continually, are discharged from the body only at intervals; and some of them have appropriate reservoirs for their reception. To this law there are two exceptions, the cutaneous perspiration and the exhalation from the lungs. The saliva, the schneiderian mucus, and the tears may be considered as finding their way, in part at least, down the gullet, and are retained in the body by the sphincter of the alimentary canal. The urinary bladder constitutes an important reservoir of this nature, which by the due performance of its retentive function, saves us from a very loathsome and painful infirmity, named *incontinence of urine*. In every case where the urine, though but a small quantity be collected in the bladder, is forced off without the voluntary effort of the individual, or flows from him unconsciously, he is truly said to labour under incontinence of it, or *enuresis*. The urine thus constantly escaping from the bladder, soon produces in the surfaces with which it comes in contact, redness, minute vesicles, pustules, excoriations, and at length ulcerations. The patient's clothes, being kept moistened with the same fluid, exhale an offensive ammoniacal odour; and thus he is not only subjected to the distressing itching and pain of the excoriations, but becomes an insupportable annoyance to those around him. The urine being decomposed by exposure to the air, the phosphates are formed and deposited in the surface over which it flows, and hence we have often in cases of enuresis small particles and thin crusts of gravelly substance, which serve to increase the irritation of the excoriated parts.

Incontinence of urine exists in different degrees, being in some cases so complete that the fluid drains off continually by the mere effect of gravity, as if the bladder and urethra were without life; in others it is discharged at short intervals in small quantities, by the involuntary contraction of the bladder; or this occurs only during sleep; or the urine is retained by the patient while at rest, but when he moves about, it flows off, notwithstanding all his efforts to retain it. Sometimes the degree of exercise required to produce incontinence of urine is considerable, as in the instance of a woman cured of vesico-vaginal fistula, who was a servant in a small tavern: she could retain her urine perfectly excepting on market-days, when she was subjected to much fatigue, running up and down stairs.*

Causes.—The immediate cause of enuresis is in all cases a greater or less defect in the muscular fibres which close the external orifice of the bladder, and to which the name of sphincter may with perfect propriety be applied.† This defect in the muscle which op-

* Edin. Med. and Surg. Journal, vol. xxi. p. 62.

* Christison on Poisons, p. 456.

† Ryan's Med. Jur. p. 133.

poses the escape of the urine may be either positive or relative. Positive defect in the sphincter may consist in a debilitated or paralysed state, or in its inefficiency from an aperture existing in some part of the bladder. Relative defect in the sphincter, on the other hand, consists in its inadequacy to resist the strong and sudden contractions of the expulser of the urine, which thus overcomes the closing muscle, and reduces matters to the same state as if the sphincter were actually debilitated. But we are inclined to think, that in most of those cases where the body of the bladder is morbidly irritable and prone to contract on a slight stimulus being applied, the sphincter is in like manner prone to dilate and to yield to the pressure of the urine, which indeed is quite in accordance with the natural sympathy of the parts.

Paralysis of the sphincter of the bladder arises from the various diseases and injuries of the brain and spinal chord which give origin to other palsies; and it is occasioned likewise by injury or disorganization of the nerves which immediately supply the neck of the bladder. A state of debility, or an approach to paralysis of this part, may arise from injuries inflicted upon itself or its immediate vicinity: such as the operation of lithotomy, the dilatation of the part in the extraction of calculi without incision, repeated laborious parturition, suppurations in the vicinity of the neck of the bladder, the operation for fistula in ano, injury of the bladder by its displacement, as in cystocele, prolapsus of the uterus and rectum, pressure from the gravid uterus. Many females in the latter stages of pregnancy cannot cough or laugh loudly, or make any sudden movement without causing the involuntary discharge of a small quantity of urine. The sphincter of the bladder may also be so weakened as to produce enuresis, by a long continuance in the cold-bath, by habits of immoderate indulgence in sexual intercourse, and by solitary vice; the first of these causes acting as a direct sedative; the two last as indirect ones, by inducing at intervals excessive and prolonged turgescence of the genital organs, and consequent debility.

The retaining power of the sphincter of the bladder is completely destroyed by the formation of an aperture in that organ in or beyond its neck; as in vesico-vaginal fistula, in fistulous openings between the bladder and rectum, or between the bladder and the external surface of the abdomen, and in fistula communicating with the ureters or kidneys. The same will be the effect in all those cases of deficient congenital formation where the cavity of the bladder communicates directly with the surface of the body,* and where the urachus remains open with an orifice at the umbilicus, or has become so in the progress of disease.

Instances of the relatively deficient power

of the sphincter of the bladder are presented by most of those cases of nocturnal emission of urine which are met with in children; and the same morbid sensibility of the bladder occurs also in old men, and is productive of the same consequence—enuresis.

The irritability of the bladder may be augmented by many causes, of which the most frequent are calculus and disease of the prostate gland; fungous growths within the bladder have also the same effect; and it is produced likewise by the presence of worms within the rectum, and by other irritations of neighbouring parts. Enuresis depending on a convulsive contraction of the muscular tissue of the bladder takes place during the paroxysm of epilepsy, and, in a less severe degree, occasionally in chorea and hysteria; also from the sudden impression of cold in the genitals, and from the influence of sharp unexpected pain. It is told of an Italian coachman that, when he wished his horses to stale, he seized their ears between his teeth and bit them smartly, which never failed to produce a flow of urine. The effect of piercing sounds, as the notes of the Scotch bagpipe, in causing involuntary contraction of the urinary bladder, has often been remarked; and common observation must convince us how powerfully this organ is influenced by fear and anxiety of mind.

Enuresis in children usually ceases after the second dentition, and very rarely persists beyond the full development of the genital organs at puberty; except, indeed, in cases of mental imbecility, where its continuance is to be referred to the same cause which produces the inability to retain the saliva, and the tottering step and awkward movements of the idiot.

Incomplete enuresis may also be produced by a diminution of the cavity of the bladder, which renders it impossible for the person to retain more than a very small quantity of urine; and in such cases there usually exists at the same time a morbid irritability of the body of the organ.

Treatment.—In enuresis, as in most other symptoms of disease, the mode of treatment will depend on the cause of the affection; and by its removal we shall in general accomplish a cure. When the power of the sphincter of the bladder is positively weakened, we must employ the most approved means of restoring the nervous energy of the part, as friction, rubefacients to the loins and sacrum, the affusion of cold water on the spine, blisters to the lumbar and sacral regions, electricity, galvanism, stimulating enemata; the internal use of cantharides, strychnine, tonics, such as quinia, nitrate of silver, arsenic, steel, copper, zinc, and the vegetable bitters. When incontinence of urine depends on the existence of a fistulous opening in any of the urinary cavities, the aid of surgery must be called in; but if all attempts at a cure fail, one of the many ingenious mechanical contrivances for such cases must be had recourse to, and the situation of the patient rendered as comfortable as this distressing infirmity will permit. Un-

* *Duncan*, Edinburgh Med. and Surg. Journal, vol. i. *Baillie*, Morbid Anat. *Meckel*, Handbuch der Patholog. Anat. b. i.

der these circumstances the greatest attention must be paid to personal cleanliness; and the ammoniacal smell which is so liable to be produced ought to be corrected by means of one of the vegetable acids, such as the acetic or tartaric. In almost all cases of enuresis from malformation, this palliative plan is the only one which affords any prospect of benefiting the patient.

When enuresis proceeds from a disproportion between the contractile power of the body of the bladder and that of the sphincter, or, in other words, from a morbid sensibility of the bladder to the stimulus of the urine, attention to the general health and to the state of the bowels is especially required. The irritability of this organ must be allayed by large doses of opium and hyoscyamus given in enema or suppository, and, if necessary, by the mouth; and all irritations of neighbouring parts, such as from worms in the rectum, must be removed. As this form of involuntary discharge of the urine occurs most readily during sleep, certain precautions are required before the patient goes to rest.

Nothing of a diuretic nature should be taken at any time of the day, and no liquids swallowed for some hours before bed-time: the patient's bed should consist of a mattress with a moderate covering of bed-clothes, and he should recline on his side and rather on his face, for the contractions of the bladder seem to be excited by the urine resting on the sensitive surface between the orifice of that organ and the openings of the ureters.* Nocturnal enuresis occurs under different circumstances—from the sleep being so profound that the child is not awakened by the stimulus of distention which precedes the expulsion of the urine, or from his dreaming of voiding it, or, lastly, from an indolent disposition, which prevents him from attending to the first call to evacuate the bladder. The importance and necessity of cleanliness must be carefully impressed on the youthful mind; for by mistaken indulgence we may prolong the habits of early infancy into the period of advanced childhood. We are, therefore, clearly of opinion that when the frame is not debilitated, and when the precautions already noticed have been taken, a little wholesome chastisement will in such cases of enuresis be highly proper: it will render the sleep less profound, the dreams less delusively vivid, and serve to dispel the apathy of the indolent and the slothful. But far be it from us to recommend the revival of those punishments invented by the cruel ingenuity of former times, such as causing children subject to this infirmity to crush mice to death in their hands, to submit to the loathsome infliction of having live toads suspended from their necks, and to sit by the bed-sides of the dying. When the habit of nocturnal enuresis is deeply rooted, punishment, even the mildest, cannot be frequently repeated; but an attempt should be made to correct it by calm admonition, and endeavour-

ing to awaken a sense of shame. If increasing years do not bring with them a cure, great benefit will be derived from forcibly confining the urine within the bladder: it will tend at once to interrupt the habit, and to rouse the irritability of the sphincter. Where the jugum penis has failed, a speedy cure has been accomplished by strapping a bougie along the lower surface of the penis, so as to render the canal quite impervious to the urine.*

The urethra of females being short, and the bladder often subjected to great distention, enuresis is with them sometimes very obstinate, and requires for its cure a certain turgescence of the genital organs. Thus, when the disease does not yield to the change produced at the period of puberty, it may be removed by the internal use of cantharides and by marriage. The following fact will serve to illustrate the efficacy of turgescence of parts on the functions of the bladder. A middle-aged female, who had suffered for years from calculus, and was voiding her urine in dribblets every few minutes, had the stone extracted by dilatation, and for a fortnight thereafter retained her urine like one in health; but when the swelling from the operation subsided, incontinence came on, and continued for months to resist the various remedies employed for its cure.

When enuresis in the aged depends on a morbid sensibility of the bladder, we have found great benefit from the use of balsam of copaiba; but in many of these cases the functions of the bladder are disordered by habits of intemperance, which must be corrected before we can expect any remedy to produce permanent relief.

(W. Cumin.)

INCUBUS, (from *incubo*, to lie or sit upon,) *nightmare*: an affection coming on during sleep, and characterized especially by a sense of weight on the chest, with an inability to move, and sometimes even to speak. Various affections attacking a person during sleep produce sensations, often very uneasy, but insufficient to awake him completely; and although his eyes may be open, and he may be conscious of surrounding objects, he labours under the fancies of some horrible dream excited by the sensations in question. It is this state of imperfect possession of the faculties, and the absence of volition, which gives the peculiar character to the disease called incubus, or nightmare; and this circumstance would entitle it to be considered as much a mental as a bodily disorder. The causes of the sensations are, however, physical, and it is against these principally that treatment can be directed.

The usual and severe form is that in which the patient, in the midst of his sleep, generally in the first part of the night, becomes conscious of the sensation of a huge weight on his breast, which oppresses and impedes his breathing. This is accompanied by a feeling

* C. Bell, Treatise on the Urethra, &c.

* *Hyslop*, London Medico-Chir. Trans. vol. vi.

of inability to move, and often to speak, which greatly increases the discomfort; and the fancy, ever active, embodies these phenomena into some monster, overpowering and crushing the body. Hence the superstitious names, *nightmare*, *incubus*, *succubus*, *ephialtes*, &c. In many instances the feeling of weight or pressure is less defined; but there is a sense of general restraint and uneasiness which the mind converts into some imaginary danger, such as falling down a precipice, being pursued by an armed enemy or savage beasts, and the like, with a feeling of weight on the limbs, and an inability to escape; and this becoming so intense as to break the remaining tie of sleep, the person awakes with a start, and under the temporary alarm of this imaginary evil.

Nightmare, in all its varieties is, then, a disorder of the function of sleep, (if by such a name we may designate a suspension of other functions,) and it becomes an interesting matter of further inquiry, inasmuch as it in a degree presents an analysis of the state of sleep itself. The power of volition, both in mind and body, is that which is the most completely suspended in natural sleep. Sometimes the other mental faculties are equally so, but more generally there are trains of thought going on; and simple sensation, although blunted, is never entirely suspended. Dr. Alison has well established the opinion formerly entertained by Whytt, that respiration is an instinctive motion excited by the sensation of black blood in the lungs; and the movements and changes of posture unconsciously effected during sleep, seem to be of the same kind, and scarcely coming under the head of voluntary motions. When sleep is coming on, there is, first, an indisposition to perform voluntary acts, and if no awakening cause be applied, this soon amounts to inability. But the senses may still be awake, and although volition cannot shape or direct them, trains of ideas result from their impressions. When sleep becomes more perfect, however, the senses become more obtuse, and, unless excited by some considerable impression, incapable of influencing the other mental powers that may remain still in activity. Such an impression, when produced, if of the painful kind, and insufficient directly to awake the person, will not fail to excite some or other of the varieties of nightmare. The form which it assumes will depend on the nature of the bodily impression, and it will be sufficient to illustrate the subject by one or two examples.

In the case to which the term *incubus* or *nightmare* is commonly applied, that, namely, of a sense of weight and oppression on the chest, there is, we believe, an imperfect performance of the function of respiration, caused either by a constrained posture or distended stomach; or in some cases it may be by a slight attack of asthma, excited by acid or other crudities in the alimentary canal. Now such slight impediments during our waking hours are easily obviated by the supplementary aid which voluntary efforts can give to the respira-

tory process: we change our posture, draw our breath more deeply, relieve the stomach by eructation, &c.; and all this with scarcely a consciousness of the ailment, or of the act which relieves it. But during sleep these movements are not at our command; the respiratory act is more limited, and although sufficient for the natural state of the function, becomes inadequate when an embarrassment renders necessary an increased exertion or new movement. In event of this, therefore, black blood gradually accumulates in the lungs, with its consequent effects of congestion in the right cavities of the heart, and feeling of oppression and suffocation, which, after tormenting the mind for a time in some demoniacal form, at length reaches such an acme, as to break the spell of sleep, and awake the sufferer to the possession of those voluntary powers, by the exercise of which the bodily function is restored to its natural state. No sooner is he fully awake than the bodily uneasiness is removed, and he is sensible only of the mental disquietude which his frightful dream has occasioned; and this, joined with the excitement of the restored circulation, may prevent him from readily composing himself to rest again. This we conceive to be a sufficient explanation of the phenomenon of nightmare; without resorting to hypothetical notions of pressure on the solar plexus or nerves of the stomach, which, if capable of producing an effect at all, should do so equally beyond the period of sleep. Incubus may, therefore, be justly placed in contrast with somnambulism, in which the power of voluntary motion continues, whilst the external senses are either suspended, or their impressions superseded by some internal train of ideas that engrosses the mind.

As causes of incubus, we have already named disordered digestion and constrained posture; and we may now add diseases of the heart, and whatever is capable of interrupting, during sleep, the due arterialization of the blood.

We pass on to notice some other causes which may produce effects of analogous character. Such are, pains of any kind, as tooth-ach, ear-ach, &c. which, when insufficient to prevent sleep, often become the demon of a dream, tormenting the sufferer in a thousand different shapes. Cold feet are another common cause of disordered sleep. There is, however, between these causes and that which produces nightmare, this difference; that in the case of these, the person awakes to a consciousness of the real cause, whereas the sensation of nightmare ceases with the return of voluntary movement.

Various impressions on the sense of touch may engender disturbances of somewhat similar character. On this subject some remarks by the most celebrated writer of our day are too philosophical to be omitted here. "There is one circumstance in which the sense of touch is very apt to betray its possessor into inaccuracy, in respect to the circumstances which it impresses on its owner. The case occurs during sleep, when the dreamer touches with his

hand some other part of his own person. He is clearly, in this case, both the actor and the patient, both the proprietor of the member touching, and of that which is touched; while, to increase the complication, the hand is both toucher of the limb on which it rests, and receives an impression of touch from it; and the same is the case with the limb, which at one and the same time receives an impression from the hand, and conveys to the mind a report respecting the size, substance, and the like, of the member touching. Now, as during sleep the patient is unconscious that both limbs are his own identical property, his mind is apt to be much disturbed by the complication of sensations arising from two parts of his person being at once acted upon, and from their reciprocal reaction; and false impressions are thus received, which, accurately inquired into, would afford a clue to many puzzling phenomena in the theory of dreams. This peculiarity of the organ of touch, as also that it is confined to no particular organ, but is diffused over the whole person of the man, is noticed by Lucretius:—

‘ Ut si forte manu quam vis jam corporis ipse
‘ Tute tibi partem ferias, æque experiare.’

A remarkable instance of such an illusion was told me by a late nobleman. He had fallen asleep, with some uneasy feelings arising from indigestion. They operated in their usual course of visionary terrors. At length they were all summed up in the apprehension that the phantom of a dead man held the sleeper by the wrist and endeavoured to drag him out of bed. He awoke in horror, and still felt the cold dead grasp of a corpse's hand on his right wrist. It was a minute before he discovered that his own left hand was in a state of numbness, and with it he had accidentally encircled his right arm.*

Another case, which Dr. Abercrombie in his interesting work “On the Intellectual Powers,” cites from the late Dr. Gregory, is clearly one of the same character with nightmare, and well illustrates our explanation of its pathology. “Dr. Gregory mentions a gentleman, who, after sleeping in a damp place, was for a long time liable to a feeling of suffocation whenever he slept in a lying posture; and this was accompanied by a dream of a skeleton which grasped him violently by the throat. He could sleep in a sitting posture without any uneasy feeling; and after trying various expedients, he at last had a sentinel placed beside him, with orders to awake him whenever he sank down. On one occasion, he was attacked by the skeleton, and a severe and long struggle ensued before he awoke. On finding fault with his attendant for allowing him to lie so long in such a state of suffering, he was assured that he had not lain an instant, but had been awakened the moment he began to sink. The gentleman after a considerable time recovered

from the affection.”* In this case, we have little doubt that there was a real constriction or spasm in the glottis, or some of the air-passages, which became sensible only in the confined posture of recumbency, and during the low respiration of sleep.

We have little to say of the treatment of nightmare, as it must depend on the correction of its several causes. Of these, too much or undigested food is among the most common; hence the propriety of prolonging the period between the principal meal and the hour of rest, as well as of avoiding crude and indigestible articles of food. (See INDIGESTION.) The symptoms of acidity and flatulence are to be treated in the usual way, by magnesia or alkalies, and essential oils or other carminatives; and when these fail, ether will often succeed in relieving the stomach of wind, and the nervous palpitation which often follows an attack of nightmare. Nor is it unimportant to pursue measures to prevent the recurrence of this disorder; for besides that it

“ — makes sleep a pain,
And turns its balm to wormwood,”

the disorder that it occasions in the circulation may, in those predisposed, bring on a fit of epilepsy or apoplexy, which not unfrequently occur during the first sleep.

(C. J. B. Williams.)

INDIGESTION.—This word is synonymous with *dyspepsia*, (from *δυσπεψία*, to digest with difficulty: Th. *δύς* and *πέψω*;) and signifies interrupted, laborious, or painful digestion; or, in other words, any derangement of that function by which the aliment, after having been received into the stomach, is converted into chyle.

The function of digestion is in its nature complex, consisting of the harmonious action of an apparatus of several organs, all mutually dependent upon the action of each other. These organs, singly, are liable to be disturbed by many different causes, which may each be again modified in their operation by a multitude of secondary and adventitious circumstances; and as every separate organ must perform its part healthily to complete the general function, so also the disorders of each individual organ may induce various derangements in the action of the whole apparatus. This view of the matter may give us some notion of the necessary diversity of the disorders of the function of digestion, and may serve to shew us that, whatever common denomination we may employ to denote its general derangement, we must comprehend different disorders, having their seat in different organs, depending on different morbid conditions, presenting various forms, induced by various causes, and all necessarily demanding various corresponding methods of cure. For though the disorder of one of the subordinate processes may induce the interruption or the disorder

* Sir Walter Scott's Letters on Demonology, p. 43.

of the whole function, and thus may seem to lead only to the same common disease, yet even under this supposition it is not immaterial to ascertain where and in what manner the faulty series has commenced, whether the impediment may have arisen in the stomach, the duodenum, the liver, or in any other organ; but it is also necessary to be acquainted with the particular modification of the function of either of these organs, for in this consists the nature or proximate cause of the disease: just as in the derangement of a watch, though the motion of the entire mechanism may be arrested by the disorder of some of its parts, the artist finds it necessary to discover in which the error lies, whether in the spring, the verge, or the balance, and whether the fault consists in excess or in deficiency of momentum or of matter.

That which physiology leads us to anticipate, observation fully confirms; for pursuing a contrary course of investigation, tracing effects up to their causes, we shall have still greater reason for admitting the diversity of the disorders of the function of digestion. Thus it would be contrary to all the common principles universally admitted in reasoning concerning natural phenomena, to suppose that the most opposite symptoms could arise from the same pathological state of the digestive organs,—that causes the most contrary could induce the same morbid condition, and that methods of treatment in direct opposition to each other could generally overcome one and the same disordered state. Thus,—that an impaired and fastidious, and a keen, craving, insatiable, nay, bulimious appetite; that an unquenchable thirst and a complete disrelish for liquids; that painful sensations of the stomach excited by the presence of food, and others relieved by the presence of food; that pain before eating and pain after eating; that an exalted sensibility of the organs rendering the patient painfully conscious of the whole process of digestion, and a diminished sensibility of the stomach by which a patient, though suffering from, is altogether unaware of, any disorder of the digestive function; that the more easy digestion of solid food by some, and of liquids by others; the agreement of fat or oily substances with some, of albuminous with others; of saccharine matter with one, acidulous with another; that a deranged state of this function, constantly accompanied with a moist, pale, white, or coated tongue, or with a clean, dry, red, appearance of the tongue; with a clammy, moist, perspiring, or a dry, shrivelled, impervious skin; with unhealthy, fetid, alvine discharges, or with evacuations which betray no sign of disorder; with a perfectly healthy state of the urine, and a highly unnatural state of that secretion; not to mention secondary and sympathetic affections, various, contrary, and incompatible with each other;—that all these discordant symptoms should emanate from one and the same morbid condition of the digestive organs, is a supposition altogether incomprehensible, and totally at variance with the acknowledged laws of

order, constancy, and consistency, which regulate natural events.

In the same manner,—that fasts and surfeits; that repletion and starvation; that taking food too frequently and fasting too long; that the richest viands, the most refined preparations of food, and cold, crude, vegetable fare, without seasoning or condiment; that the varied repast of the most pampered, with every thing to whet and every thing to sate the appetite, and the simple scanty food, greedily devoured for very existence, (whether the potatoe of the poor Irish, the oaten cake of the Scot, or the salted and smoked fish of the Swedish peasant—all three well known to be equally great sufferers from dyspepsia); that wine-drinking and water-drinking; that dry diet and fluid diet; that excessive indulgence in sleep and overwatching; that inactivity of body and excessive fatigue; that indolence of mind and intense bent of thought; that the ennui of the fashionable idler, and the wearisomeness of the artisan; that the anxious cares of business, and the languor of inaction; that dwelling in dry, warm, badly ventilated apartments, and constant exposure to cold moist air; that the too frequent use of the warm bath, and the habitually squalid unwashed skin:—that all these ordinary causes of dyspepsia, so much at variance with each other in their nature and effects, should yet conspire in producing only one disease,—only one pathological condition of the digestive organs,—involves the absurd conclusion, that in the actions of the human body the most opposite causes have, in similar circumstances, the same identical effects.

And no less from the different nature of the means by which the disordered conditions may be corrected or removed, than from those by which they may be induced, shall we have reason to affirm that the derangements of the function of digestion are many and various: or we must suppose that a dry and a fluid diet; that a full diet and a scanty; that one of animal food and one of farinaceous; that a stimulating diet and a cooling; that distilled or fermented liquors and water; that alkalies and acids; that bitters and sweets; that tonics and demulcents; that stimulants and refrigerants; that repletion and depletion; that sipping brandy and sipping ices; that heat and cold; that the warm-bath and the cold-bath;—that means so dissimilar and methods so repugnant to each other, have yet the same operation upon the living body.

From this diversity of symptoms, of causes, and of means of cure, it is more reasonable to infer a corresponding diversity in the morbid condition of the digestive organs, than to embrace the absurdity,—belied by all experience, and only consistent with our superficial learning in the language and grammar of the Book of Nature,—that the same things can have contrary signs, or that in similar circumstances opposite causes can produce the same effects.

It may seem that on this point,—the different nature of the disorders of the function of digestion,—we have insisted too much; and indeed we should have thought it unnecessary

to have pressed upon the attention of the profession a matter of such obvious importance, had we not occasion daily to observe the general tendency to apply to all these disorders the same method of treatment, as if they invariably constituted merely one and the same disease. The late Dr. Cullen, by affixing a general term to these disorders, may be justly charged with having in no inconsiderable degree promoted this error; but we are likewise not aware that any writer has felt more forcibly than himself its practical inconvenience. "We have established," says he, "a genus of disease under the title of Dyspepsia, and perhaps there was no avoiding it, but it is too general, and under this generality of little use. It comprehends every irregularity in the functions of the stomach; but these are certainly of great diversity in their nature and causes, and we want more accuracy and precision than we yet have."* In this circumstance of the great diversity of diseases comprehended under one common name, has originated the chief impediment to the successful medical treatment of dyspepsia; for it is self-evident that, as its different forms require to be met by corresponding methods of cure, the skill of the physician must mainly depend upon the power of distinguishing them, so as to be enabled to apply to each particular form of disorder its especial remedy, and also to adapt as nearly as possible the modification of the treatment to the modification of the disorder. The perfection of medical skill is most unquestionably the talent of applying to each individual case its precise, and, as it were, its individual cure,—an object which, though difficult of attainment, ought nevertheless to be the constant aim of the physician—the object which he ought unceasingly to pursue, and never rest until he has overtaken. Furthermore, we are very much inclined to suspect that a great part of the real secret of specific remedies lies in this, that they, being only applicable to diseases of one form and few specialties, are on this account alone so constant in their effects. In some degree in confirmation of this opinion, we may observe that when any specific disease, by complication or otherwise, assumes any remarkable deviation of character, then the specific remedy becomes dispossessed of its power. So that the success of these remedies does not so much depend upon any exclusively specific relation between the nature of the medicine and the nature of the disease, (for we know that syphilis is to be cured by other medicines than by mercury; that psora is curable by hellebore as well as by sulphur; that agues may be arrested by arsenic as well as by quinine,) but upon the medicine having the power of curing a disease which is comparatively constant in its character, its operation not being liable to be frustrated by any peculiar modifying circumstances;—the disease thus specifying the remedy, not the remedy the disease.

This view of the matter should afford us

reason to hope, that if in diseases less constant in their character and more variable in their accidents, we could meet the specialty of disease by its corresponding specialty of cure, we might also hope for an equal success, of which we have already some example and foretaste in the method of treating some diseases; as, for instance, in the plan of cure followed so successfully by the Pères de la Charité in colica pictonum. It should also teach us that, instead of ransacking every kingdom of nature for specific remedies,—a pursuit literally preposterous,—it is more reasonable, and would most certainly turn to better account, to seek for specific diseases, or by a proper specification, which is the very spirit and essence of practice, to endeavour to make them such. This is the object we have chiefly in view in the following article,—rather a sketch than a treatise of dyspepsia,—namely, to decompose the false and artificial genus comprehended under this term, to endeavour to establish a natural one in its stead, and by a proper classification of causes, symptoms, and methods of cure, to distinguish and define the different kinds of the disorders of the function of digestion,—*eorum tempora et causas in quibus medicinæ summa est*,*—so as to be able to establish a more close and accurate relation between each variety of disorder and its most appropriate remedy, in order that more certainty and more success may attend its application. "Ideoque dubitandum non est, quin si medici, missis paulisper istis generalibus, naturæ obviæ ire vellent, compotes ejus fierent, de quo ait poeta :

" ' Et quoniam variant morbi, variabimus artes ;
Mille mali species, mille salutis erunt.' "†

On reviewing the labours of our predecessors, we are confirmed in these opinions, for we find that the best observers have recognised great diversity in the disorders of the function of digestion, and that though, masking them each with his own particular theory, they have disguised them under particular names, there remains a remarkable coincidence in their observations and in their principles of distinguishing them. Thus we find that Hippocrates‡ made a distinction between gastric and intestinal dyspepsia, to which corresponded the *passio stomachica et ventriculosa* of the Methodists.§ This distinction was revived by Hoffman|| and others, was insisted upon by Pinel,¶ and indicated by Ferriar** and Warren,†† but was never accurately and precisely laid down before the able and useful lecture of Dr. G. D. Yeats upon the diseases of the duodenum.‡‡ Thus Celsus establishes several different disorders of the function of digestion, founded chiefly upon the different morbid

conditions of the organs, to each disorder assigning its appropriate remedies.* In the different disorders of the digestive organs noticed by Celsus, not, however, to be all admitted as species really distinct, might no doubt be found most of those recognised by more modern writers; the simple dyspepsia of the solidists, the chylopoietic disorder of Mr. Abernethy, and the chronic gastritis of Broussais. In the disorders of the function of the stomach the Methodists acknowledged two principal divisions, *stomachica passio solutionis et stricturae*,† which were again by many of the sect variously subdivided. The former we shall find equivalent to the simple dyspepsia of the moderns, but in the latter may be found a strong resemblance to the dyspepsia from morbid sensibility and irritability of the stomach noticed by Cheyne,‡ Whytt,§ and Pemberton,|| but more insisted upon of late years by Barras¶ and Dr. James Johnson.** Others, building upon shifting quicksands, founded the distinction of the different kinds of dyspepsia upon their symptoms; and thus Galen, who defined dyspepsia to be any depravation of the alimentary mass in the stomach by which it was changed into something different from its natural product, distinguished dyspepsia into two species, *nidorous* (κνιδώδης) and *acid* (ὀξύδης), marking two of the most ordinary effects of indigestion. In this principle of distinction, Galen was followed by the symptomatic nosologists, who carried it to such a height, that the disorder was decomposed into all its various symptoms, each being made to constitute a distinct and independent disease.

To this error Cullen opposed another, still more pernicious, for he gathered together all the symptoms of disordered digestion, and thus formed his genus, *dyspepsia*; a genus illogically constructed, without species to support or sustain it, in which all previous distinctions were lost and confounded. Cullen, as we have already had occasion to remark, was himself more fully aware of the inconvenience of this arrangement than his followers; but it was not until—recovering the traces of the earliest physicians, and following the more recent examples of Dessault, Richter, Schmucker, and Scarpa,—after having incurred the just criticism of Fischer, a German, and having had the subject boldly unfolded to them by Halle,†† a

Frenchman, and when the attention of the medical profession of England had been fully concentrated on the disorders of the digestive organs by the writings of Dr. Hamilton* and Mr. Abernethy,†—disappointed by the generic treatment, and dissatisfied with the generic knowledge of dyspepsia, observant practitioners felt the want of better distinctions; and a spirit of specification commenced, which, still in progress, is yet, we hope, far from having reached its utmost limits. Of this spirit the earliest signs, we think, are to be found in Pemberton,‡ who was followed by Stone§ and by Warren.|| It is to Dr. G. D. Yeats,¶ however, that we are indebted for one of the most important contributions. About this time appeared Broussais, a bold reformer in physis, to whom the world is under deep obligations for subjecting the nature of dyspepsia to a searching analysis, but who in exposing one error plunged into the opposite, perhaps a greater one. With the same object in view, Dr. Wilson Philip,** an original observer, pointed out some valuable practical distinctions in these disorders; and though his work may fairly lay claim to be considered the most comprehensive and the most original which we possess upon the subject of indigestion, we are of opinion that, admitting only one primary form of dyspepsia, he laid too narrow a foundation for rearing a complete and correct classification of this disease. Other candidates have since appeared in the same field of enquiry, who have more or less helped towards the completion of this work. In chronological order, we find Dr. Ayre,†† who has chiefly considered one form of the disease; our esteemed friend, Dr. Marshall Hall,‡‡ a physician of fine and distinguishing observation, who, under the term of *mimoses*, has treated the subject of symptomatic diseases with much judgment and discrimination; Mr. Law,§§ who has made some original observations on the various kinds of costiveness; Dr. Paris,||| who, from the physiology of the function of digestion, has deduced some valuable conclusions concerning its disorder; Dr. James Johnson,¶¶ who has checked and corrected the hasty generalization of Broussais and his adherents; our excellent friend Dr. James Clark,** an acute and a scrupulous observer, who has very accurately described two different species of these disorders; Mr. Cook,††† an able and

observing practitioner, who has illustrated his distinctions of the disease with very interesting cases; and lastly, Dr. Mayo,* who has called the attention of the profession to the importance of considering the influence of temperance in the treatment of indigestion. But it is due to the memory of Mr. Abernethy to state, that, though he did not co-operate in the task of distinguishing and specifying the disorders of the function of digestion, he looked forward to its accomplishment,† and insisted on its importance. It is only matter of deep regret that he should have contented himself in his first position, instead of methodizing and digesting his ample store of accumulated experience, and of thus advancing forward to the consummation of his enterprise.

Digestion, like any other function of the body, may be disordered in consequence of some morbid condition of its proper organs, or it may be disturbed in consequence of the morbid condition of the body in general, or of some organ in particular. This affords the leading division of dyspepsia into *idiopathic* or *primary*, and *deutero-pathic* or *secondary*, the most important practical distinction of every disease. But the disorder of a function may arise either from some change of action of the organ,—some new modification of its vitality,—or it may depend upon some lesion of structure; from this is naturally deduced the division of *primary* dyspepsia into *functional* and *organic*.

And as the disorder of a function may be either the effect of disease of the whole body, or of some particular organ or apparatus of organs, *secondary* dyspepsia may be conveniently divided into *symptomatic*, forming only a part of a more general disease, and *sympathetic*, the consequence of consent with the disorder of some other organ.

The disorder of the function of an apparatus of organs may either predominate in some particular organ, or may involve the whole apparatus; a consideration which, in the instance of dyspepsia, leads to the distribution of the previous divisions into four natural orders, according as the *stomach*, or *duodenum*, or *colon* is the exclusive or principal site of the disease, or as it involves more or fewer of these parts at the same time; whilst the different morbid conditions which any of the particular organs, or the whole apparatus may assume, afford an easy method of distinguishing these orders into different species. The morbid conditions by which the action of the organ may be modified, have been recognised by the best observers under the terms, *atonic*, *irritable*, *inflammatory*, and *follicular* or *pituitous*: in these morbid conditions, easily cognizable and perfectly capable of verification by the symptoms, consist the proximate causes of functional dyspepsia. Those in which the structure of the organ is altered, admit of being distributed according to the nature of the struc-

tural lesion, or as the function becomes disordered by change of capacity, sensibility, or in its secretory function. *Symptomatic* dyspepsia might be divided into species according to the constitutional disease in which it might originate, whether fever, plethora, anæmia, asthenia, or any other form of constitutional disorder; and *sympathetic* dyspepsia would admit of a convenient division according to the organ from whose disorder it took its rise, as the brain, the lungs, the skin, the kidneys, the uterus, or any other organ.

Such is our plan of a complete natural classification of the various disorders of the function of digestion, the result of close and continuous observation, combined with a methodical arrangement of cases; those being grouped together which coincided in causes, symptoms, and means of cure; and each group being denoted by the pathological derangement on which we supposed them to depend. Pursuing this course, it will be observed that we have arrived at distinctions nearly coinciding with those of our predecessors, a strong proof of their correctness, which, verifying our observation by that of the great masters of our art, establishes these distinctions on a long line of uninterrupted experience. But before concluding this part of our subject, we must observe that, whatever objection may be taken to our pathology, to our opinions, or to the terms by which the different species are denoted, it will afford no ground for denying the existence of these species; for being founded on observation and formed inductively, they must survive any error of opinion; and the classification, being natural, has this advantage, that as any new species of disorder of the function of digestion may be discovered and ascertained, (as no doubt, hereafter, many most certainly will be), their place or niche will immediately be found without the necessity of the whole structure being broken down and rebuilt, as constantly happens with artificial classifications. The nature of the present work does not, however, admit of the possibility of following up the whole of this plan, and requires that we should confine ourselves to the first division of the subject, *idiopathic functional dyspepsia*; but we shall endeavour, by way of help, to avail ourselves of the corresponding facts of the other divisions, to confirm, explain, or illustrate any part of this. The following outline presents the plan of classification, and enumerates the several species to which we hope to be able to refer the greater part of the varieties of this disease.

IDIOPATHIC FUNCTIONAL DYSPEPSIA.

I. GASTRIC DYSPEPSIA.

The disease consisting chiefly in disordered function of the stomach.

I.—*Atonic gastric dyspepsia.*

Synonyms.—ἄπειψιν, πλυσμὸν, Hipp.; stomachi resolutio, cruditas, Cels.; frigiditas stomachi, Prosp. Alpin.; anorexia, plethorica, arthritica, paralytica; nausea a cacochylia; vomitus a saburra; flatulentia, acida, nidorosa; cardialgia a saburra, paralytica; gastrodynia saburralis, Sauvages; dyspepsia idiopathica; anorexia atonica, Cullen; saburra materiæ mobilis, Auctor. Var.; indigestion, first stage of W. Philip; dyspepsie, apyrétique, asthénique, Broussais; dyspepsie per asthénie de l'estomac, Andral; embarras gastrique.

General character.—Loss of appetite, sometimes nausea and loathing of food, with occasional inclination to vomit, but seldom sufficient to provoke vomiting; thirst after eating, not after digestion; heartburn; acid, nidorous or putrescent eructations; sense of weight at the epigastrium after a meal; power of digestion more particularly impaired as regards oily, fatty, mucilaginous, saccharine, and acidulous substances; tongue pale, flabby, whitish or slimy, more or less coated; bowels generally confined; urine clear and copious, devoid of its natural smell, deficient of urea, sometimes albuminous, and then disposed to putrefy on standing; pulse somewhat weaker, generally slower than natural; temperature of the body lower than natural and unequally distributed; extremities cold, countenance pale, skin flaccid, eye dull; listlessness in expression, languor in motion, obtuseness of feeling, mind impaired in vigour, in all things a want of alacrity.

These symptoms depending chiefly on the morbid condition of the stomach, are subject to considerable variation from the presence of crudities, being different as the stomach is full or empty. But the general character of the symptoms is not destroyed by this cause of variation; for, as the different morbid conditions give rise to different symptoms, so the presence of crudities excites symptoms, subject and corresponding to each morbid condition.

The symptoms also vary as they may happen to be direct or indirect, as they emanate immediately, from the suffering state of the stomach, or, mediately, as the suffering of the stomach is felt and reflected in the sympathetic disorder of some other organ. The variation and diversity of the symptoms of atonic gastric dyspepsia

arising from each of these sources, will be noticed in describing this disease according to the two forms under which it presents itself, as it takes place suddenly, or as the symptoms manifest themselves in a slow and gradual manner.

a. *Acute form.*—In the first case, which might for the sake of distinction be termed *acute atonic gastric dyspepsia*, corresponding more precisely with the ἀπειψιν of Hippocrates, the cruditas of Celsus, and the embarras gastrique of the French, the disorder comes on in distinct attacks or paroxysms, the patient enjoying in the intervals a comparatively healthy state of digestion. As the disease continues, these attacks are repeated at shorter intervals, whilst the interval itself becomes a state of less perfect health, and the disease, growing more and more habitual, at last arrives at that state in which disorder of the digestion is more or less constantly present, though in a degree less severe than during the intensity of the paroxysm.

These paroxysms vary in their duration from three or four to twenty-four hours or even longer, being shorter in young, and longer and more frequent in older persons and those most disposed to them. As the paroxysms are induced by accidental causes, their return is of course irregular; but, as has just been observed, the liability to them increasing with repetition, slighter causes are capable of inducing them, and they are therefore, *ceteris paribus*, more frequent in old than in young subjects, some suffering a paroxysm every two or three days, others once in two or three weeks.

The patient may have been feeling dull or heavy, have been losing his usual relish for food, may have observed his bowels less regular, or have been complaining of that peculiar sensation at the root of the tongue, and sometimes through the whole length of the œsophagus, which constitutes what is called heartburn; but as it is generally during sleep that the paroxysm comes on, it is in the morning that the symptoms of indigestion are first distinctly pronounced. The patient awakes with headach, or feels heavy and languid, devoid of his wonted alacrity, and indisposed to leave his bed. There is rather flatness than lowness of spirits, with sometimes slight confusion or indistinctness of intellect. The tongue feels clammy, sometimes it is also dry; there is generally an insipid taste, but sometimes it is milky or sweetish, occasionally sourish. The appetite is impaired or entirely deficient, sometimes with nausea, amounting occasionally to a disposition to vomit, and when vomiting does occur, phlegm only is thrown up; or there is a capricious appetite, craving for some unaccustomed kinds of food, but which are seldom agreeable if presented. When the attack is slight, the symptoms are occasionally suspended by taking some grateful food, the action and sensibility of the stomach being revived and restored by being gently solicited. Generally there is an aversion to acids, sweets, or any thing insipid. There may be heartburn, eructations of acid, of oily or rancid matter, sometimes of hepatic

gas, or a feeling of weight or load at the stomach, giving the sensation that the process of digestion is entirely at a stand. In other cases there is a sense of constriction of the fauces, with a watery secretion from the back part of the mouth. Sometimes the patient is suddenly awakened by cramp in the legs, or violent spasmodic pain in the stomach, (*gastrodynia saburrealis*,) accompanied frequently with violent retching. The face is pale, the countenance inexpressive, and the eye dull and heavy, with sometimes a dark discoloration or puffiness round the eyelids. The pulse is somewhat weaker, generally slower, usually soft, frequently languid and feeble, sometimes small and quick, occasionally intermitting. The skin is moist, clammy, and flaccid, and generally cold. The feet and hands are cold, with a general feeling of chilliness or creeping over the skin, sometimes amounting to rigors; sometimes there is a particular coldness, stiffness, or numbness of the fingers. The tongue is pale and flabby, generally moist, and covered with a loose slimy white coat, more or less thick. The bowels are constipated; sometimes there is a sensation of inaction or of dryness in them. In the commencement of the paroxysm the urine is pale and copious, less frequently it is deficient; but in its decline it becomes high-coloured and turbid, depositing a red sediment of lithic acid, or of lithate of ammonia, or the amorphous sediments of the lithates generally.

The above is an account of an attack of atonic dyspepsia connected with, or arising from, a state of repletion of the stomach; but the same state may arise from that organ being deprived of its accustomed stimulus or supply, as occurs to delicate people when they pass the hour of their accustomed meal. They have a great sense of weakness, sometimes faintness and trembling; they lose their appetite, have a bitter taste, and a sensation of weight or sinking at the præcordia; their countenance becomes pale and wan, their eyes sunk; they lose their temper and their spirits; their urine becomes hot, scalding, and high-coloured; if they attempt to eat, they have no appetite or a disgust for food, and if they eat, all their symptoms are increased. They have a difficulty in getting to sleep, or are disturbed with dreams. Giddiness, headach, coldness, trembling, constant yawning, are common attendants of this state of the stomach.

The sympathetic affection most universally connected with this form of disordered digestion is headach, which, being generally associated with nausea, is well expressed by the common term *sick-headach*.* It affects generally one particular part of the head, chiefly the forehead, or is seated over one or both eyebrows, and sometimes in the ball of the eye. The pain is heavy, dull, and overpowering, but seldom acute. With the headach, the whole nervous sensibility appears to be concentrated in the head, where it is much increased, being accompanied with intolerance of light and of

noise. The headach begins sometimes to abate on a vomiting of bitter or acid matter, but sleep is the most constant harbinger of relief. As the headach abates, it leaves a general soreness or tenderness of the head, and the squeamishness and general uneasiness continue for some time after.

The other affections frequently observed, sympathetic of *acute atonic gastric dyspepsia*, are a sensation of mistiness before the eyes, indistinctness or offuscations of vision, sometimes amounting to temporary amaurosis, and more rarely, dilatation of the pupil, without any defect of vision; deafness, and sometimes unusual sounds in the ear; loss of smell or taste, or depravation of these senses, so that unnatural smells and flavours are perceived, when there is no external impression; in delicate and sensitive persons, fainting, and in women hysterical fits occur; trismus, convulsions, and, in those predisposed, a fit of epilepsy; loss of voice, paralysis, a fit of apoplexy; spasmodic cough, a fit of asthma or of angina pectoris; neuralgia and various local pains, temporary delirium, a fit of mania, urticaria, erysipelas, and some other cutaneous affections. But many of these complaints are more especially connected with one of the effects of this disorder, distention of the stomach, the direct symptoms of which are restlessness, a sense of oppression, and anxiety.

Causes.—This particular form of dyspepsia most frequently makes its first appearance in early and middle life, from puberty to the age of thirty, less commonly after forty. Women are more subject to it than men. It is more common in cold than in warm climates, in cold than in warm weather; but moist climates and moist weather, whether warm and moist or cold and moist, have a great influence in predisposing to it. The middle and upper stations of life are most exposed to it. The predisposition to this complaint is sometimes hereditary, the person inheriting a relaxed constitution, or one of exalted nervous sensibility, but of weak powers; for it affects rather the cold phlegmatic and the asthenic habits than the sanguine or bilious temperaments; and chiefly those of that peculiar relaxed constitution characterised by want of firmness, resistance, and elasticity, by a soft relaxed skin of a pale colour, by a tendency of the hands and feet to be cold, by a languid circulation, by the functions of the body being imperfectly performed, either less actively or irregularly, and by the secretions being rather disposed to be copious than scanty. But this particular constitution may be also acquired by certain habits and manner of living, as by want of exercise, by indolence of body, by indolence as well as by intense or long application of mind, disproportionate to the strength of the body; by effeminate habits and enervating excesses, by the too frequent use of the warm-bath, by dwelling in close, warm, ill-ventilated apartments, by sleeping in hot soft beds, and by over indulgence in sleep. The habits of certain trades and professions contribute considerably to this disease; the confinement to

* *Fothergill*, Med. Obs. and Inq. vol. vi.

the desk, the sedentary occupations of sempstresses, milliners, mantua-makers, and tailors; those of the loom, of the tambour, of the stocking and lace-frame, and of laundresses who work much over a stove. For all these various reasons, this complaint prevails more in the town than in the country,* and is, as it were, endemic in the boarding-school, the boudoir, and in manufactories; at court, at college, and in prisons; and under the title of *asthenia* has been very well described by Dr. Willan in his account of the diseases of London. The habit predisposing to this disease may also be a consequence of loss of blood, excessive suckling, seminal weaknesses, leucorrhœa, or any cause which exhausts or debilitates the system in general; of the habitual use of narcotics in excess, as tobacco, conium, or henbane, which injure the sensibility of the nervous system. But the cause which has the greatest influence in disposing to this disease above all others, is habitual incaution in diet, both in respect of kind and quantity of food; for it matters not whether the stomach be frequently offended by that which it cannot subdue, or morbidly distended, and thus rendered incapable of appropriating that which is wholesome. For this reason offences against quantity are not less injurious than offences against quality, and both are doubly baneful when the repast consists of many kinds indiscriminately mixed. To these may be added an irregularity in the times of taking food, the meals being sometimes too frequently repeated, or the intervals too long protracted.

Where the predisposition is strong, or the patient has suffered long, slight causes are sufficient to produce a paroxysm of this form of dyspepsia; but where even neither natural nor acquired predisposition exists, certain circumstances are capable of producing an accidental fit of dyspepsia, and of thus laying a foundation for its recurrence. Amongst such may be enumerated any sudden or unusual disproportion or want of due relation between the digestive organs and the ingesta, a neglected state of bowels, intense application or strong emotions of mind, especially soon after a meal. A sudden fit of passion, or great joy, will sometimes instantly produce this affection. They will also sometimes remove it; "We have more than once," observes Pemberton, "known a necessity for a great exertion of mind to supersede the stomach affection, which has re-appeared on the necessity being withdrawn." Violent exertions or much fatigue of body, either immediately before or soon after a repast; any causes which induce sudden distention of the stomach, as a bulky meal of soft, sweet, pultaceous food, over-indulgence in fruit, large quantities of cold, iced, warm, acid, or sweet fluids suddenly swallowed, more particularly if the process of digestion is still in progress; a sudden change of diet from animal to vegetable food; mucilaginous drinks, &c. eating hastily after fasting too long, missing the wonted meal, or taking it

out of season; taking a cold or warm bath immediately before or soon after a meal; medicines, particularly calomel, conium, henbane, digitalis, ipecacuanha, especially administered at an improper period of digestion; venesection when performed soon after a meal, or leeches applied to the epigastrium under the same circumstances. In the delicate and predisposed, we have observed it excited by variable weather, by exposure to a cold and moist atmosphere, by the application of cold to the skin, particularly to the lower extremities, by sitting in a room of low temperature, so low as to cause a sensation of chilliness, by a change of wind, particularly from a north to a south-west gale.

b. Chronic form.—In this form of indigestion, which might be termed *chronic atonic gastric dyspepsia*, the *πλησμονή* of Hippocrates, the disorder creeps on in a slow insidious manner, and becomes scarcely apparent until it has existed for a considerable time. Some of the following symptoms, more or less grouped and combined together, afford indications of its approach: drowsiness in the day, particularly after a meal; sleep deep, heavy, prolonged beyond the usual hour; the sleep ceases to be refreshing and is disturbed with uncomfortable dreams, sometimes with incubus, and the patient awakes in the morning feeling fatigued, and having a disagreeable taste in his mouth;—less aptitude for exercise, frequent stretching and yawning, torpor or sluggishness in movements, which begin to require a greater effort; diminished activity of mind, mental occupations becoming laborious; diminished enjoyment of the natural appetites, less relish for food, by degrees diminished appetite, especially for breakfast; a sensation of heaviness in the head, of fulness or itchings in the forehead, of fulness or stuffing in the nostrils, particularly after a meal, with a frequent desire to emulge them; a feeling of huskiness in the throat, particularly in the morning, with expectoration of a grey, viscid phlegm, and sometimes an increased flow of saliva. A sensation of fatigue and weariness, sometimes amounting to pain, begins to be felt in the whole or in particular members of the body; a heavy dull pain in the head with drowsiness, a sensation of weight at the stomach, heartburn, or a sensation of internal heat after meals, more especially after breakfast; and the bowels begin to be habitually constipated. These symptoms are followed by distention after eating, by flatulence when the stomach is empty, at first relieved but afterwards increased by eating; by eructations of the last meal, sometimes acid, sometimes putrescent; by change of complexion, paleness of the face, which is bloated; by deficient alvine evacuations, altogether disproportionate to the ingesta, sometimes by diarrhœa of liquid and undigested food, which affords temporary relief; or by perspiration on the slightest exertion. The disorder may continue for a considerable time in the degree manifested by these symptoms without producing any serious derangement of the health; and, by change of habits, of air, and of

* At imbecillis stomacho, quo in numero magna pars urbanorum.—*Celsus*.

exercise, they may be entirely removed. But the long continuance of the disorder brings other derangements. The bowels become habitually confined, and there is a constant sense of fulness, distention, and dryness in them. The repasts cease to be pleasant or satisfactory, but are always followed by oppression; the extremities are generally cold, the power of exercise begins to diminish, the patient begins to lose flesh, and has a constant sensation of weakness, faintness, or trembling, or is troubled with vertigo or headach, with noise in the ears, throbbing of the temples, cough or fits of palpitation. The mouth feels clammy; the tongue is more or less furred, or has a whitish sodden appearance; sometimes the saliva runs from the mouth, and there is a viscid frothy secretion from the fauces, or there is frequent spitting. The skin is generally moist and clammy, sometimes cold; and perspiration is excited by the least exertion. The urine leaves a coating of lithic acid at the bottom of the utensil. The powers of the intellectual faculties, particularly of attention and memory, are remarkably diminished; the feelings are obtuse and little alive; the patient begins to feel flat, dull, and timid without reason, or sinks into a state of apathy or indifference, whilst the physical sensibility becomes morbidly increased, manifested by a remarkable sensitiveness of changes of weather, particularly of the approach of moist weather or storms.

The further course of the disease is generally very much influenced by the use of remedies, and by the different methods of treatment had recourse to; for if not properly administered, they are mainly instrumental in determining various forms of dyspepsia hereafter to be described. If the disease be allowed to follow its natural progress, it terminates by inducing a disordered state of the function of the duodenum and liver. More rarely the disease undergoes an entire change, which occasionally leads to a natural cure, in consequence of a fixed point of irritation becoming established in the intestines, the activity of the stomach is excited and increased, and the disease is transferred to the intestines in the form of diarrhoea, which, subsiding spontaneously or artificially, leads to a permanent relief of the primary disorder; but which continuing lays the foundation of a form of inflammatory dyspepsia to be treated of in the sequel of this article.

Causes.—This variety of atonic gastric dyspepsia is, with some exceptions, the consequence of the same causes as those which give rise to the first variety. It is less the effect of hereditary disposition, and more the result of the remote causes of dyspepsia operating insidiously upon a healthy constitution. In this way it is induced in people of regular and orderly lives, who seldom commit any offence against temperance or sobriety, and in people of sedentary, monotonous, indolent habits. It affects literary* and professional people, clerks, shopkeepers, and is met with in all constitutions, but in men rather than in women; it occurs generally late

in life, and prevails most in winter. A disproportion between food and exercise is the great cause of this disease; but indulgence in much warm liquid, as tea, pre-eminently the English breakfast, in relaxing slops, in meals too frequently repeated, deluging the stomach with tea whilst digestion is in progress, and the habitual use of malt liquor, are the most fertile sources of this disorder.

Pathology.—The morbid condition of the stomach, from which proceed the various symptoms of atonic dyspepsia, has been recognised by the very earliest physicians* under the term of *atony*, or some word of corresponding meaning, as *asthenia*, *relaxation*, *resolution*, or *debility*; and instead of this morbid condition of the stomach having been overlooked as the proximate cause of indigestion, it has, on the contrary, been too generally admitted, and the species of dyspepsia which is now under our consideration has accordingly been made to represent the whole genus, every symptom indicative of indigestion, every sign of chylopoietic disorder, having been attributed to debility or want of tone of the stomach.

A state of collapse, of deficient vital power or nervous energy, under various modifications and descriptions, has, as we have already observed, been universally admitted ever since the phenomena of life have been an object of observation. By the operation of certain causes the whole body may be involved in this morbid condition; by their more partial application particular parts or individual organs only may be placed under its influence. But as it is the nature of the body for a part to assume the state of the whole, and for the whole body to partake of the action of a part, whether the disorder be at first induced in the general system, or only in some particular part, in either case they both ultimately arrive at, and terminate in, the same condition. The digestive organs are not exempt from the operation of causes capable of inducing this morbid condition, and when the stomach, more especially, is placed under its influence, the disorder of the digestive function which we have just described is the consequence.

But by the term *atony* of the stomach we express a general and complex condition, resolvable into several subordinate or particular ones; for under it are included—1. a deficient innervation of the stomach, by which some unknown vital action is withdrawn, and the natural affinities of the constituent elements of the alimentary mass, instead of being directed and controlled, obey the laws of inorganic matter, rather than the special influence of organic life; 2. a depraved or deficient secretion of the gastric juice; 3. a diminution of the absorbing power of the stomach, by which the digestion of liquids is rendered more difficult; and, 4. a diminution of the contractile power of the muscular fibres of the stomach, by which this organ is prevented from compressing its contents, as in health, that the food and gastric

* Omnesque pæne cupidi literarum.—Celsus.

* Ἀτονίᾳ τοῦ πέψοντος ὁρμητοῦ, καὶ ψύξι τῆς κοιλίας.
—Arctæus.

juice being brought into contact may be exposed in successive and appropriate portions to each other's action.

It would not be difficult to trace the process by which the causes of dyspepsia induce the foregoing results. If we consider the nature of their operation, we shall find that they admit of a classification corresponding to the several morbid conditions just enumerated. Thus by sedentariness and repletion is destroyed the healthy equilibrium of waste and supply; for, as has been well observed, as, by virtue of the consent of every part of the living body, all the functions of assimilation can only be preserved in health so long as the stomach digests well, so on the other hand the stomach can only digest well so long as the different functions which convey and deposit the nutritious matter in the various tissues are healthily performed, which, however, cannot be the case when from indolence or similar causes there is both a deficient consumption of this nutritious matter, and a defective elimination of the effete and worn-out particles. The consequence is, that the whole process of nutrition languishes, and the stomach losing the stimulus of demand fails in its activity. This principle, recognized so early as Hippocrates in his famous dictum, *δίότι οὐ δύναται ἐσθίειν ἄνθρωπος ὑγιαίνειν, ἢ μὴ καὶ ποιεῖν*, explains the operation of many of the causes of dyspepsia, shewing how they may induce a deficient innervation of the stomach; and this will be the result whether the equilibrium be destroyed from the consumption being deficient or the supply being excessive. Then we may again observe that some causes induce the same effect by destroying the corresponding and harmonious action of the different parts of the alimentary canal; others by diminishing the natural sensibility of the stomach, either directly, as narcotics, or indirectly, by concentrating the nervous energy in the head, by intense thought and application; whilst others arrive at the same result, diminishing the innervation of the stomach, by withholding or diverting from it a proper and sufficient supply of blood, from which results an unhealthy and insufficient supply of the gastric juice; very contrary to the opinion of Parry, who attributes idiopathic dyspepsia to a morbid fulness of the vessels of the villous coat of the stomach. Other causes act by diminishing the contractile power of the muscular coat of the stomach, either by producing a relaxed state of its fibres, or by sustaining them in a state of unnatural distention, by which they lose the power of resuming their natural state: others effect their deleterious influence by withdrawing from the stomach the healthy and accustomed stimulus which calls it into action, so that it not rarely happens that, after having been more or less stimulated, withdrawing suddenly every source of excitement, the stomach falls into the opposite state, one of perfect atony; and this frequently occurs, whether it be the body in general, or the stomach in particular, which is deprived of its wonted stimulus and excitement.

This view of the operation of the causes which induce atonic gastric dyspepsia, and of the various morbid conditions which they produce, we shall find very much confirmed by considering the state of the body and of other organs in those cases in which this form of dyspepsia is secondary, whether symptomatic of general disorder, or sympathetic of the disorder of some particular organ; for we shall find that the dyspepsia of simple general plethora,* of asthenia or general debility,† whether induced by venereal excess or weakening discharges, of general anemia,‡ whether from loss of blood, or disorder of the process of sanguification,§ and the dyspepsia of gout,|| all belong to this form. In like manner we shall find that the dyspepsia sympathetic of cerebral irritation,¶ of hydrocephalus, of vertigo** and nervous headach, from accidental injuries of the head, from the action of narcotics upon the nervous system, as tobacco, digitalis, hemlock; the dyspepsia which follows a fit of inebriety,†† the dyspepsia of constipation, the dyspepsia of some forms of disordered uterine function, the dyspepsia of rigid continence,‡‡ and the dyspepsia which alternates with an atonic state of various other organs,§§ belong also to this form. The dyspepsia which is produced in animals by the division of the eighth pair of nerves, offers a strong analogical proof of the same position.

We may also find the view we have taken of the proximate causes of atonic gastric dyspepsia amply confirmed by examining cases of dyspepsia from organic lesion; for we shall find that, as the organic changes approach the morbid conditions of this form of dyspepsia, the symptoms of atonic gastric dyspepsia are present. Thus, when the stomach has been found unusually large and distended, with or without obstruction of the pylorus;|||| thus also in induration and thickening of the coats of the stomach;¶¶ in the early stage of diseases of the pylorus, or where there exists any obstruction to the egress of the chyme from the stomach;*** in atrophy of the mucous and muscular coats of the stomach; or when the stomach has been found lined with a false membrane; in the softening or solution of the mucous membrane of

the stomach,* to which we may add anæmia of the alimentary canal, which is always accompanied with more or less attenuation of the coats,—a pathological state not rarely presented to the anatomist, but chiefly observed in the bodies of those exhausted by chronic diseases, or who sink during the convalescence of a severe fever;†—in all these cases the disorder of the function of digestion approaches the form of atonic gastric dyspepsia. But though approaching and resembling each other, the two disorders afford data of distinction; 1. by the absence of sympathetic affections; in the organic diseases of the stomach, the sympathetic headach and other disorders being never observed; 2. by the stomach being the seat of painful affections; 3. by the greater constancy and invariableness of the symptoms; and, 4. by the attendant emaciation.

Method of cure.—The treatment of *atonic gastric dyspepsia* is conveniently divided into the means of affording relief when the disorder is actually present, and the means of preventing its return.

I. The means of affording relief when the disorder is present consist in, 1. removing crudities or offensive substances directly from the stomach by vomiting; 2. in endeavouring to remove indigestible substances from the stomach, and restore its action by exciting that of the intestines; 3. by allowing the stomach to repose until its action begins to revive, and by soliciting its action as its sensibility returns; and, 4. by relieving the secondary affections which arise from the disordered function of the stomach.

1. Emetics afford the proper means of removing offending substances from the stomach. In the beginning of a fit of dyspepsia, in the earlier period of the disease, or in cases of accidental dyspepsia, an emetic frequently at once arrests the progress of the disorder, and we have known some persons subject all their lives to frequent paroxysms of the acute form of this disease, who have experienced more relief from emetics than from any other remedy. If, however, the paroxysm has continued long, or the disease has become habitual, they cease to bring their former relief, and, when unnecessarily administered, are always pernicious; ‡ for vomiting, whether spontaneously occurring or artificially excited, becomes itself a frequent cause of stomach complaints. It was a remedy much used and abused by the Romans, affording them the means of indulging their gluttony; *qui quotidie ejiciendo vorandi facultatem moluntur*: but it is a short-sighted compromise, granting no impunity; it changes but does not take away the penalty of the vice.

The immediate symptoms which more particularly indicate the administration of an emetic are nausea, a sense of weight at the præcordia, bitter eructations, the internal sensation of crudities, the mouth overflowing with saliva, and paleness of the countenance.

* *Ramollissement des Vieillards.*

† Andral. Path. Anat.

‡ *Inutilis est gracilibus et imbecillum stomachum habentibus.*—*Celsus.*

When vomiting is strongly indicated, it is easily excited. The gentlest means are therefore to be preferred, warm water, simple, or containing a little culinary salt, warm infusion of chamomile flowers, infusion of mustard-seed, and ipecacuanha, are means of different degrees of power which may be occasionally had recourse to; sometimes simply titillating the fauces answers every purpose. After vomiting, cold water is the best remedy for restoring the stomach; in summer iced water; sometimes Seltzer water. These should be sipped in small quantities at a time. After a proper interval a small quantity of light palatable food may be taken.

2. By virtue of the sympathy which exists between different parts of the alimentary canal, the function of the stomach is frequently restored by exciting that of the bowels, and therefore, when the attack has continued beyond that state in which emetics promise relief, or when they have failed of relief, purgatives are to be had recourse to. They should consist of such as are warm in their nature and speedy in their operation, but neither stimulating nor drastic. Rhubarb is decidedly the best. It may be advantageously combined with, and modified in its action by, magnesia, by carbonate of soda, by tartarized potass or soda, in conjunction with some aromatic or carminative distilled water, with a small quantity of the tincture of rhubarb or compound decoction of aloes, and a little of the compound spirit of lavender, or aromatic spirit of ammonia, as the state of the stomach or accompanying circumstances may suggest or indicate. In this form of dyspepsia senna is not proper, and saline purgatives alone are injurious, as are also the mercurial purgatives.

It is generally necessary to continue to promote the action of the bowels during the decline of a fit of dyspepsia, and for some days afterwards. For this purpose a few grains of rhubarb, in combination with a little soda or carbonate of ammonia, taken an hour before the two principal meals, answers very well; or the following formula of Fothergill affords a remedy well suited to this intention:

Rx Aloës ʒi.

Rad. rhei, rad. glycirrh. aa ʒʒss.

Spirit. lavand. comp. ʒʒss.

Aq. calcis ʒviii.

Infunde per horas xii et cola. Colaturæ cochl. duo bis terve die sumenda. On some occasions it suffices to relieve the bowels by clysmata, and when this method is found to answer, it is always to be preferred.

3. It would seem unnecessary to insist on the necessity of abstinence during a fit of dyspepsia; but it is not always superfluous, for the morbid sensations of the stomach sometimes imitate, and are readily construed into, that of hunger. They ought not, however, to be listened to, for abstinence is the chief remedy. The patient may drink, from time to time, a small cup of green tea, without sugar or milk, or a cup of coffee, moderately strong, with as little as possible of those ingredients; or he may take a small quantity of light pure broth,

sufficiently sapid to be agreeable, with a small quantity of stale bread or dry toast. As the natural sensibility of the stomach returns, it may be solicited by a little animal food, such as is palatable and easy of digestion. If the patient is accustomed to the use of wine, but not otherwise, it may be necessary to allow a moderate quantity with the meat: the red wines for this purpose are generally to be preferred. Farther than this the stomach is not to be excited. All such means of doing so, as brandy, capsicum, or food containing it; mustard, piquant sauces, curries, or high-flavoured dishes, are to be avoided. In this category we would also place bitters, and those medicines improperly termed stomachic. The action of the stomach ought never to be hurried or forced by stimulants; it can only bear them when its function has been already to a certain degree restored. Before this period they only tend to fix the disease. The state of the tongue affords the best guide for the use of food and its quality; as it is moist and disposed to clean they are admissible, and as it is dry they are to be forbidden.

4. Besides the general treatment of a fit of dyspepsia, there are painful symptoms and sympathetic affections which ought not to be overlooked, and, indeed, the relief of which is not without its influence upon the primary disease. But in administering means of relief for such affections, it is important to take care that they do not oppose, but are made subservient to, the plan of general treatment.

Heartburn.—Dr. Fothergill's formula, mentioned above, affords a good corrective of this symptom; *magnesia, liquor potassæ* (gut. x. pro re natâ), *ammonia subcarbonas* (gr. v.), lime-water; sometimes alkalis combined with bitters. We have found Seltzer water a very excellent remedy; and at other times repeated small quantities of very cold or iced water, taken when the stomach is empty. Heartburn which is habitual or of long standing is sometimes more effectually relieved by acids than by alkalis. Pemberton mentions having seen it subdued by the juice of half-a-dozen lemons taken daily, and recurring on the remedy being left off; but we imagine that the heartburn here meant is not that which proceeds from acidity, but the burning sensation depending upon a heated state of stomach, a symptom of another form of dyspepsia. In heartburn nitric acid is also a useful remedy; five drops of the diluted acid may be taken every four hours. We have also used successfully the phosphoric acid with the same intention, and have found it more agreeable to the stomach.

Flatulence.—This symptom is best relieved by combining a carminative with the aperient. Equal parts of the *pil. rhei comp.* and *pil. galbani comp.* form a convenient remedy; carbonate of ammonia in mint-water; very hot water in small quantities after a meal, is sometimes found a very efficient corrective of this symptom.

Distention of the stomach from flatulence to an extreme degree, in old people, is often attended with alarming symptoms, sometimes

convulsions, sometimes apoplexy. By extreme distention the muscular coat loses its contractility, and the mucous membrane its sensibility, and thus the usual remedies lose their power. In such cases mustard poultices applied to the pit of the stomach are of great service, whilst the internal means are put in use. The best of these are ammonia in infusion of horse-radish or of mustard-seed, and repeated draughts of water as hot as it can be taken. In extreme cases the use of the stomach-pump should not be omitted.

Nausea and vomiting.—When these symptoms continue after the stomach and bowels have been satisfactorily relieved, effervescing saline draughts, especially those prepared from the subcarbonate of ammonia, are suitable remedies; to these, if the symptoms are urgent, may be added a little spirit of lavender, camphor julap, and, in case of necessity, one or two minims of the "black drop." The hydrocyanic acid (gut. i ad ii.) has been also used with considerable advantage; but we believe it to be more efficacious in the other forms of dyspepsia.

Headach.—When this symptom does not subside with the primary affection, it may be relieved by valerian (tr. valer. ammon. or infus. valer.) either alone, or combined with camphor; if attended with sleeplessness, a small dose of pulv. *ipeacuanhæ comp.* may be given in camphor mixture, or a saline draught; or if heartburn be present, may be combined with *magnesia* or *liquor potassæ*. But a warm pediluvium, containing mustard or culinary salt, or evaporating lotions of vinegar, spirits of lavender and rose-water, applied to the head, are sometimes more efficient than internal remedies.

It would be extending this article too far to enter into the treatment of the other various secondary affections of this disease; we must content ourselves with referring to the symptomatic form of each of these disorders.

II. Having afforded relief to the urgent state of indigestion, it is the duty of the physician to direct his attention to the means of obtaining a permanent cure, which consists more in prevention than in positive remedies. The object to be held in view in the prevention of a disease has been clearly and succinctly expressed by Celsus—"quod vel corporis vel loci, vel studii ratio detrahit, cura restituit." Guided by this general view, seeking if possible to avoid or remove, if not to counteract the causes of the disease, we shall endeavour to fulfil this intention by indications derived from the nature of the operation of the causes in which it originates, and from the morbid condition of the stomach in which it consists. These indications serving as principles to direct our prophylaxis, and applicable, with some small modification, to every form of dyspepsia, may be stated to be—1, to render the process of digestion as easy as possible by a selection of food of a quality suited to the nature of the disease, and by a proper adjustment of the quantity suited to the power of digestion; 2. to excite the function of nutrition by proper exercise of body and mind; 3. to correct the

morbid condition of the stomach, the proximate cause of the disease.

1. This is beyond all comparison the most important point in prevention of this disease; the reducing the quantity of the food to the power of digesting and of appropriating it, instead of yielding to the cravings of a pampered appetite. The change ought to be brought about gradually, for in that way it is most agreeable to the habits of the body, and most likely to be persevered in; and if the diminution of diet is made with judgment and selection, it ought to be effected by withdrawing from it such articles of food as are difficult of digestion, and such as have a tendency to weaken the stomach. This object is best attained by confining the patient to a small spare diet of animal food, with considerable restriction in the use of fluids. It is in this form of dyspepsia that so much benefit has been obtained by strict adherence to a dry diet, and by avoiding a bulky meal. When the appetite flags, abstinence will be found a better whet than cordials, stomachics, or dainty fare. When the appetite does not fail, the patient should finish his meal without waiting for the sensation of satiety, taking care that he be not deceived by a morbid craving, the offspring of disease and bad habit, not, of health.* When any doubt as to quantity may arise, he may be assured that it is safer to err by taking less than enough than more than enough—"nunquam utilis nimia satietas, sæpe inutilis nimia abstinentia."

For breakfast coffee is to be preferred to tea, and should be taken with as little milk and sugar as possible, and with a moderate quantity of bread, which, with a little fresh butter, should form the repast. It is necessary that the bread should be limited, for if taken in excess it is a common cause of heartburn after breakfast. The dinner should consist of the lean of animal food, chiefly mutton, poultry, venison, game, with the exception of hare. Roast meat is to be preferred to boiled. Vegetables are to be eaten sparingly, or entirely abstained from; mealy potatoes mixed with the gravy of the meat, asparagus, soft young summer turnips, cauliflower, or French beans, are the only kinds admissible. Rice mixed with the gravy of the meat will be found a good substitute for vegetables. Eggs lightly boiled may be occasionally used. The fruits the least offensive are strawberries, the morel cherry, and the mulberry; but they should be eaten in the early part of the day, and never after dinner. Fluids must at all times be taken with the greatest moderation; the patient should not yield to every slight sensation of thirst; they should be taken slowly, a small quantity at a time, and should follow, never precede the meal. If the weakness of digestion or habit demand a stimulus, port wine and water or sherry and water are the best; malt liquors are to be particularly avoided. Three moderate meals is the best general rule for the periods of eating, taking care to eat nothing in the intervals, and avoiding suppers. It may be stated also as a general rule, that the food and drink in this form of dyspepsia should be

taken decidedly hot or cold, not tepid; that twice dressed meat should be scrupulously avoided; and that the meat should be eaten slowly, and thoroughly masticated.

It may not be easy to say strictly what kinds of food are wholesome and what are unwholesome, but there are some so decidedly so, that there can be no dispute about them. Dr. Mandeville's definition of wholesome, "what you like and does one no harm," allows a deceitful latitude to dyspeptics. The admonition of Celsus carries a stronger impress of wisdom and experience; "non quicquid boni succi est, protinus stomacho convenire, neque quicquid stomacho convenit, protinus boni succi est."

The kinds of food most decidedly injurious in this form of dyspepsia, and therefore to be avoided, are—fluid food, more especially that which is sweet, mucilaginous, or acid, such as contains much milk; all pultaceous diet, puddings or compound dishes, particularly meat pies or meat puddings; new bread, particularly with butter; heavy unfermented bread; hard-boiled compact fat dumplings; all preparations of milks, whether custards, creams, curds, or cheeses; all fat meat, particularly pork or bacon; all young meat, and all the gelatinous parts of meat; all salted or smoked meat; strong broths, gelatinous soups, or highly concentrated dishes; fish; melted butter, oil, sauces, spices, condiments, and pickles; all vegetables, more especially roots, with few exceptions,* particularly peas, beans, cabbages, waxy potatoes, cucumbers, and pot-herbs generally; fruit in general, whether fresh or preserved, jellies of fruits, figs, dried as well as green, currants, gooseberries, pears, apples, plums, apricots, melons, and all kinds of nuts or kernels; mushrooms, truffles, and morels; treacle and honey; malt liquor, particularly ale; perry, home-made wines, punch, shrub.

2. In the early stage of dyspepsia an increase of exercise admits of greater latitude of diet; when more advanced, it affords no exemption from strictness of regimen. But by exercise we do not mean those nominal kinds in which half of the body only is exercised, as a quiet sauntering walk, or the passive exercise of a carriage;—we understand active exercises, in which every part of the body is more or less in motion, sometimes one, sometimes the other. In persons of weak digestion the ancient physicians used to insist upon the exercise of the superior extremities, and we fully understand the nature of their advice.† It is impossible to lay down any precise rule for the extent of exercise, which must be proportioned to the strength and even the habits of the patients;

* The abstinence from vegetable food, which is a painful privation to most persons, might possibly be obviated by using a digester, by which the vegetables might be submitted to a temperature considerably higher than that of boiling water. The ancients considered the cabbage race of vegetables as rendered more wholesome by boiling them in two waters.

† Maximeque quæ superiores partes moveat, quod genus in omnibus stomachi vitiis aptissimum est.—Celsus.

but it should be continued for at least two hours daily, and be sufficient in degree to produce gentle perspiration.* The patient should by degrees overcome his habits of sedentariness, commencing by taking gentle exercise on foot and horseback between breakfast and dinner; he should then extend the period of his exercise, and, if possible, rise in the morning so as to allow of a little before breakfast; but this should always be the least fatiguing. As his strength increases, he may proceed to more active exercises, strong enough to excite perspiration, but not fatigue; such as walking over unequal ground instead of plain, climbing ascents, rowing, digging in a garden, cutting and clearing wood, drawing weights over a pulley, turning a heavy windlass, as in grinding malt; military exercises, drilling, or the gymnastic exercises; or such amusements as field-sports, as coursing, fox-hunting; swimming; or such active games as cricket, fives, racket, bowling, foot-ball, fencing, the broad-sword or single-stick, or playing at quoits. Sometimes it is necessary to impart interest to exercise. In such cases gardening, agricultural occupations, the practical study of botany, geology, entomology, have been found of eminent service. On this subject Dr. Cullen says, "as a bodily exercise I can say that walking has good effects. I have always thought it necessary to continue other amusements or business; and there are several instances of persons, who have long laboured under weakness of the stomach, being cured by watching the concerns of their farm, which obliges them to be much in the open air, and in constant gentle exertion. I have cured weak stomachs by engaging the persons in the study of botany, and particularly in the investigation of our native plants, and in other gentle and long-continued amusements, such as our game of golf."† It was observed during the late war, that many of our tradesmen who joined the volunteer corps, were, by their regular military exercises, entirely cured of their dyspepsia. When the weather does not admit of exercise in the open air, reading aloud, reciting, singing, flute-playing, the dumb-bells, battledoor, dancing, skipping, and such-like, afford useful substitutes.

Exercise should always precede a meal, and never follow it; neither should the patient sit down to eat in a state of fatigue or exhaustion. A little interval between exercise and eating is on that account desirable; and this interval would be advantageously employed in gentle friction with a flannel glove, (made best of a piece of coarse blanket,) or the flesh-brush. No active exercise should be used for at least two hours after eating.

It is an old rule of philosophy as well as of physic, that the body cannot be properly exercised without the mind, nor the mind without the body. This rule emanates from the twofold function of the nervous system, which

not only supplies the vital energy or power by which the entire process of organization is carried on, but also that by which the more distinctive offices of animal life, intelligence and voluntary motion, are performed. If the power of the body be occupied exclusively in either of these, the other languishes. Many familiar illustrations of the truth of this position will readily present themselves. Long-continued or intense application of the mind does not derange the function of digestion negatively, by interfering with the opportunities of exercise, but positively by withdrawing a portion of the power by which it is carried on. Indolence of mind, on the other hand, does not interfere with the function of digestion by withdrawing the power, but by withdrawing the stimulus, the pleasurable enjoyment which well-regulated occupation of the mind imparts to the whole functions of life. The functions of digestion may be deranged by three different states, obtaining between the exercise of the body and the occupation of the mind: 1st, the most usual, a total inaction and inaction of the body may coincide with a fatigued and exhausted state of mind; 2dly, a state of indolence and sluggishness of mind, with inaction of the body; or, 3dly, a fatigued and exhausted state of body may coincide with a wearied and worn state of mind. The two first cases only apply to the present form of dyspepsia, and the indications deducible from them readily suggest themselves. The studious should, therefore, relax from their application, nor urge and overstrain the attention too long and too far; and though entire repose may not be allowed, their studies may be varied, that the different faculties of the mind being exercised* may relieve each other. It was a correct observation of a learned physician, that indigestion follows learning as close as the shadow follows the body. "Omnesque pæne cupidi literarum" Celsus considers the most constant sufferers from dyspepsia; and Aræteus has painted with his most vivid colours the painful sufferings which await a devotion to science and letters, *δείας μὲν μαθήσεως πρὸς*, when ill regulated and unrestrained. If study cannot be dispensed with, at least all application soon after a meal may be abstained from.† The indolent, on the other hand, should seek occupation, and thus avoid the pains of inaction. But in making these changes, care is to be taken to avoid running into the opposite extreme. Fatigue of body discomposes the sedentary, vacuity of mind is irksome and oppressive to the learned and to the man of business, and much study or business overcomes the indolent. Let them seek, then, occupations in which exercise, amusement, and interest may be happily combined, for they may rest assured it is a policy both narrow and short-sighted, which does not allow some hours a day to the care of their

health. "Quem interdiu vel domestica vel civilia officia tenuerunt, huic tempus aliquod servandum curationi corporis sui est."*

3. This indication; correcting the morbid condition upon which the disease depends, according to our pathology, subdivides itself into (a) endeavouring to restore the harmonious action of the different parts of the alimentary canal; (b) restoring or increasing the activity of the excretory organs, and (c) restoring the tone, or improving the innervation of the stomach.

a. To restore the corresponding and harmonious action of the different parts of the alimentary canal. In health there exists a sympathetic relation and corresponding action between the different portions of the alimentary canal. Whilst some are in action, others are in repose, or the action of one part induces that of another. This relation is most remarkable between the stomach and larger bowels; and it is frequently one of the first effects of the operation of the causes producing dyspepsia to destroy or derange this relation; either by the patient not lending a ready obedience to the calls of nature, by losing the habit of it, or, by the sensibility of the stomach becoming altered, the natural intimation ceases to be transmitted to the bowels, and then the parts lose their correspondence. This state is to be corrected by endeavouring to restore the habit of a daily evacuation after the first meal, which is natural to most people in health. For this purpose the water-closet is to be visited even when there is no call from nature. When this does not succeed, the patient may relieve the bowels every second morning by a lavement of warm water. He should only have recourse to aperients when neither of these means succeed, but which will seldom be the case if he has observed those rules of diet, exercise, and occupation pointed out in the first indication; and whatever artificial means he may have recourse to, he should every now and then afford nature an opportunity of righting herself. Another method in common use, that of resorting to vegetables and fruit and coarse bread, seldom succeeds in this form of dyspepsia, or does so only temporarily; a mild aperient is on the whole more expedient and less pernicious. The best form of aperient with which we are acquainted is the pulv. aloes comp. (gr. v.) or the following:—R. Pulv. aloes spic., pulv. rhei, pulv. g. guaiaci aa ði. Pulv. ipecacuanhæ gr. iv. Ft. pil. xii. Una vel binæ pro re natâ sumendæ. The pil. galban. comp., the pil. scillæ comp. may be sometimes advantageously substituted for the guaiacum. From five to ten grains of the inspissated residuum of the evaporated decoct. aloes comp. prepared with carbonate of soda instead of potass, or of the baume de vie, affords a mild and easy aperient.

The physician should be economical of his means, and not expend his resources unnecessarily. By this precaution he will both spare the power of the organ and of the remedy.

* Celsus.

If the habitual use of aperients is established, their power must be increased, and at last even strong remedies fail in their effect. The limitation of Celsus, with regard to aperients, is consistent with his wonted prudence; "dum et modo et non nisi quum opus est adhibeatur;" and his reason in accordance with daily observation, "assuescit enim non ali corpus, et ob hoc infirmum erit." This morbid condition will be also corrected by the means used for invigorating the function of the stomach itself. The restoration, however, of the natural relation of the stomach and bowels often suffices to restore the healthy action of the stomach and of the whole function of digestion.

b. The equilibrium of supply and waste of the body may become deranged through inactivity of the excretory organs, a common effect of sedentary and indolent habits, and not always removed upon changing them. The bowels, the skin, and the kidneys may become torpid in their action; the effete parts not being carried off, the process of nutrition flags, and the digestion fails; a stagnation takes place in the extreme vessels, the whole reproductive processes go on sluggishly, or are entirely at a stand, and the stomach in this way loses its stimulus and impulse. This state is to be corrected by giving activity to the excretory organs; and it is a method of restoring the equilibrium often had recourse to, but ought only to be used when the foregoing methods fail; for it is neither so safe, so salutary, nor so permanent as increased exercise and diminished diet. We have frequent instances of its efficacy in the use of alterative remedies, as is shewn in the vigour of nutrition which sometimes follows a course of mercury, or a course of alterative mineral waters. When expedient to be used, a continued course of alterative saline purging affords the best means of effecting it, and most efficiently the mineral waters of Carlsbad or Marienbad.

Besides these means of restoring the desired healthy equilibrium of supply and waste, it has been observed that the same may be temporarily obtained by diminishing the volume of the circulating fluid; and on this principle many cases of this form of dyspepsia, originating in a bloated or plethoric state of the system, have received considerable relief by letting blood. It is a plan well to know, but seldom to be followed.

c. The morbid condition of the stomach which constitutes *atonic gastric dyspepsia*, may be corrected, and the tone of the organ restored, either directly by means applied to the stomach, or indirectly by means acting upon the system at large.

1. Of the direct means which have the power of rousing and invigorating the stomach, in our opinion wine in moderate quantity is not only the most grateful but the most useful. The dry wines are to be preferred, as pale old sherry, diluted with equal parts of water, or old port wine and water, good claret, or white hermitage, sauterne, or hock. Some persons find a little brandy and water agree better than any kind of wine. It is sometimes of advan-

tage to administer these stimulants very cold or very warm, but never of a tepid temperature.

The medicines comprehended in the list of bitters, tonics, and astringents, have also, in a certain degree, the power of correcting the relaxed state of the stomach. But their power in this respect has been very much overrated, which has led to their abuse, and to the exclusion of more rational and successful means. According to our experience the following are the medicines of this nature best suited to this disease:—lime-water, alone or mixed with some aromatic or carminative water (the distilled water of orange flowers best conceals its taste); the infusions of calumba, chamomile, cascarrilla, orange-peel, or wormwood, alone, or in combination with carbonate of soda, or ammonia; camphor julap, mineral acids, the acid. sulphur. aromat., the diluted sulphuric acid combined with tincture of hops, or tincture of cardamoms; the phosphoric acid in the same way; the metallic tonics, as the tr. muriatis ferri alone, or in infusion of quassia, the subnitrate of bismuth, or the sulphate of zinc.

Of all the remedies of this description the best are the carbonated chalybeate waters, as those of Spa, Pyrmont, Swalbach, and Eger, on the continent, or their imitations so accurately and scientifically prepared by Dr. Struve at Brighton; or those of Tunbridge Wells. In administering these remedies, it ought not to be forgotten that they are contra-indicated if any derangement of the biliary secretion be present.

The intention of this indication is sometimes more safely and completely fulfilled by combining tonics with aperients, as the powder of calumba with rhubarb and carbonate of soda, sulphate of iron with extract of aloes, subnitrate of bismuth with rhubarb and aloes, the sulphate of quinine with aloes, or extract of colocynth.

The stomach may also be acted upon by external local applications, as by warm stimulating plasters, but more efficiently by the cold douche to the region of the stomach, or to the back opposite to the stomach. The ancients held this remedy, to which they gave the name of *cataclysmus*, in high estimation.* They used chiefly the cold douche, either of sea-water or of mineral springs. Those of Cutilia, Simbruinum, and Nepete, were most in repute, now almost unknown; for the modern Italians prefer the indulgence of the thermal springs, which they use in precisely the same manner.

2. The indirect means of restoring the tone of the stomach consist in avoiding all the causes which tend to weaken, enervate, or exhaust the body or mind, as over-indulgence in sleep, and hot beds, lustful excesses, hot and ill-ventilated apartments, moist climates, the too frequent use of the warm bath; and

correcting or removing those habits or states of body which have the same effect, as leucorrhœa, or other weakening discharges; habitual venesections, chlorosis, and such-like diseases. The hours of sleep should be diminished; the patient should retire to bed early, and should rise in the morning soon after waking; he should sleep upon a mattress, in a bed without curtains, and should be careful that his chamber is well ventilated and dry.

The clothing of the body should be rather cool than warm, but sufficient to prevent the feeling of coldness; without being oppressive it should be sufficient to protect the patient from the inclemencies of the weather. It will be at all times desirable that the lower extremities should be kept in a state agreeably warm.

If the patient have the power, he should select for his residence a dry climate, either cold or mild, such as is found in England at Brighton, Tunbridge Wells, Clifton or Malvern; in Switzerland, at Berne or Lausanne; in the south of Europe, at Nice, Genoa, and Naples. He should inhabit airy and well exposed apartments fronting the south east, so as to have the forenoon sun, and should be cautious not to dwell near rivers and marshes.*

Much of the baneful effects of prisons, manufactories, and places of a like kind, might be corrected by proper ventilation, by the use of the *cheminée d'appel* and similar expedients.

The patient should pay particular regard to cleanliness of his person; he should use freely the ablution of cold water, sometimes to the whole, sometimes to parts, of the body; he should sponge the body every morning for a considerable part of the year with cold vinegar and water, or salt and water, much used by the ancient physicians under the name of *ψυχρολουσία*—*frigidi consuetudo lavacri*—and should afterwards rub the body well with a coarse towel; at another period he may use the shower-bath, the cold sea plunging-bath, or the cold fresh-water bath, or exercise himself in swimming; and when none of these means can be used, he should not omit dry friction of the body with the flesh-brush or a flannel glove, a salutary exercise for the indolent, and a useful substitute for it in the convalescent, or those who have not the benefit of locomotive exercise. The patient should pass much time in the open air; he should change his air from the town to the country, from the plain to the mountain, from the sea-side to the inland parts;† or he may find a continued change by a well-planned, not hurried, tour, the most effectual. Of exercise as an alternative we have already spoken; as a tonic it is not less to be regarded; and to both these means—air and exercise—respiration and perspiration—we agree with Aretæus in

* *Habitare vero ædificio lucido perfatum æstivum, hibernum solem habente, cavere meridianum solem, matutinum et vespertinum frigus itemque auras fluminum atque stagnorum—ne modo frigus, modo calor noceat.*—*Celsus*.—See also *Dr. Clark's Treatise on Climate*.

† *Adhibita mutatione longâ, terrenâ et maritimâ.*—*Celsus*.

* *Hinc perfundi frigida, atque in eadem nature, canalibus ejusdem subjicere stomachum ipsum, et magis etiam a scapulis, id quod contra stomachum est.*—*Celsus*. *Ægrotante maritimæ natatione exercendi atque cataclysmo, hoc est, aquarum illusione, suppositis partibus.*—*Cæl. Aur.*

granting a peptic power greater than medicine.*

We must bring our method of curing this form of dyspepsia to a conclusion with observing that though complete success is only to be expected from a steady perseverance, it will not be so readily obtained by strict and undeviating monotony. No regimen of the body is perfect which does not admit of a change; no method is complete which does not leave room for variety. It is the nature of the body as well as of the mind to desire and require novelty. The same diet long-continued becomes loathsome, the same exercise irksome, the same occupation uninteresting, the same medicine inert and powerless. The very disease we are endeavouring to cure may in our opinion be induced by too strict an adherence to one regimen long-continued. "Quod enim consuetudinem est, nocet, seu molle, seu durum est." It is, therefore, the duty of the physician to be well stored with a diversity of means equivalent, but not identical, all capable of effecting the same object, by whose changes, substitutions, and modifications, he may keep alive the languishing resources of the body, drawing a lesson from the wisdom of nature, which has provided us with such an ample variety, that every year hath its own peculiar character, every season its food, every day its weather, every hour its temperature, and yet all are uniform, consonant, consistent, but subservient. And so our methods should be diversified in their details and particulars, but uniform in their general plan and spirit. In this principle of variety, this law of our constitution, are explained the astonishing effects of change of air and climate in the disease of which we have been treating, in which is comprehended the change of all our habits, of diet, exercise, and occupation.

But our advocacy of variety in means and method, is not opposed to perseverance in a plan of regimen, but in support of it, the most efficient way of giving it the permanency of habit and success; and even after success, neither may the regimen be relinquished. "Illud quoque in omnibus stomachi vitis præcipiendum est, ut quo modo se quisque refecerit, eodem sanus utatur; nam reddit huic imbecillitas sua, nisi iisdem defenditur bona valetudo, quibus reddita est."†

II.—*Inflammatory gastric dyspepsia.*

Synonyms.—Stomachi æstus et inflammatio, *Cels.*; passio stomachica stricturæ, et cynanche stomatica, *Cal. General character.—Painful digestion, sense of heat, tenderness, or pain at the epigastrium, increased upon taking food, or on pressure;

thirst; tongue more or less of a bright red colour, sometimes brownish red, sometimes dry, glossy, and adhesive; taste saltish or alkaline, occasionally like that of blood; bowels generally confined; urine high-coloured; skin dry, occasionally profuse, partial sweats, chiefly in the direction of the extensor muscles; temperature of the trunk increased, of the extremities diminished, except occasionally in the palms of the hands and soles of the feet, which, especially at night, are frequently dry, hot, and burning; aggravation of the symptoms under the use of stimulants or irritating ingesta.

Forms of the disease.—As this disease may present itself in different degrees of intensity, the symptoms are liable to a corresponding variation.

In its lowest degree it is not manifested by loss of appetite, but by increase of thirst, particularly during the night, by increased heat of the skin, flushing of the face, and redness of the conjunctiva, particularly after meals, by disturbed sleep, unpleasant dreams, and by the patient awaking wearied and unrefreshed. The tongue on its anterior half is of a red colour, brighter than natural, often by superficial observers mistaken for a clean tongue; it is seldom dry except during sleep, but soon dries on exposure, and is generally found in this state on awaking; sometimes there is an increased flow of saliva, particularly during sleep, sufficient to leave large stains upon the pillow. When the stomach is loaded with crudities, the tongue is covered with a brownish yellow fur towards its base. The lips are generally dry, and of a glossy red colour, the fauces dry, flushed, or erythematous. The bowels are confined, only dry scanty stools being voided; the urine is scanty, but clear and high-coloured; if any sediment be deposited, it is small in quantity, forming a thin lateritious coating on the bottom of the vessel. The pulse is somewhat harder, more contracted, but seldom much accelerated except during digestion. Contemporaneous with these may exist various secondary symptoms, such as a painful sensation of tension in the head, increased on motion and after eating, or a painful pulsating tension, sometimes a sense of fullness; pain between the scapulæ,* pain of the left side, left shoulder, or left arm, and sometimes local pains in various parts of the body, often felt most acutely on awaking; eruptions of the skin, chiefly lichen, erythema, urticaria, psoriasis, and pityriasis.

In a more advanced stage of the complaint the patient begins to refer his sufferings to the seat of his disorder. He complains of a burning pain at the pit of the stomach, which is much increased upon pressure, and after taking food; or of a sensation of oppression at the stomach, with great uneasiness and discomfort during the digestion of his food, which is generally also accompanied with flushing of the face, acceleration of the pulse, and frequently a tense pulsating headach. If the appetite is not impaired, it is sooner satisfied, and taking food

† *Celsus.*

* Dolor inter pales tenens.—*Cæl. Aur.*

sometimes causes nausea. There is considerable thirst; the face is red and swollen, the eyes are red, the lips red and parched, sometimes blistered and swollen; the tongue is either of a bright glossy red, sometimes smooth, having the papillæ obliterated, disposed to be dry and adhesive when touched, or of a brownish red colour, or presenting a red ground covered with a thin film of the colour of coffee; small vesications or ulcerations are common upon the tongue, upon the inside of the lips and cheeks, and the mouth generally, which is also redder than natural. The fauces are also red, presenting an erythematous blush; they are generally dry, and frequently the seat of ulcerations. The taste is saltish or alkaline, frequently corresponding precisely to that produced by nitrate of potass; there is also very often a sensation of heat or of scalding at the point of the tongue, such as follows the taking very hot soup. The bowels are constipated, the urine is scanty and of a high colour; the skin dry and harsh, except during sleep, when the patient is sometimes bathed in a heavy transient sweat; the pulse is now permanently quicker than natural, small and contracted, but always quicker and stronger during the process of digestion; the temperature of the body is increased, and the patient complains of burning of the palms of the hands and soles of the feet at night; the sleep is disturbed by painful or unpleasant dreams.

The preceding symptoms, the constant signs of the disease, may be obscured or thrown into the shade by some of the more prominent secondary affections, often the chief subject of the patient's suffering and complaint, and of the physician's attention. The principal of these are headach, a tense splitting headach, increased by motion, by stooping or eating, sometimes deep pains plunging through the head; these are accompanied with a morbidly increased sensibility to light, sound, and all impressions; pain in the left side, in the left hypochondrium extending to the shoulder and arm, pain of the back between the scapulæ, particularly severe on awaking; strong and painful pulsation of the heart, increased in impulse, bearing all the appearance of hypertrophy of the ventricles; inflammation of the eyes or eyelids; soreness, redness, and ulceration of the membrane of the nose; eruptions of the skin, chiefly scaly and exanthematous; suppression of the menstrual function for a time, not unfrequently followed by increased menstruation. With these are conjoined more or less peevishness of temper, irritability of feeling, sullen oppression of spirits, anxiety or restlessness of disposition, all strongly though not elegantly expressed in the words of Cælius Aurelianus; "*animi angustia, jactatio, anxietas, sine concatenatio mentis et desponsio.*"

In a more acute degree of the complaint there is a total loss of appetite, or disgust for food, which on being swallowed causes nausea or is instantly vomited. There is an indistinct dull pain across the pit of the stomach, or a sensation of constriction as if something were

tied tightly across it. The pain is increased on pressure, and sometimes a strong palpitation is felt at the same time. Frequently the pain is felt more in the chest, or the patient complains more of darting pains under the breast, which, being accompanied by a hard dry cough, bears all the appearance of, and is not unfrequently mistaken for, a pulmonary affection, but which may be easily distinguished from it by the cough being always excited by stimulating ingesta, by its returning in paroxysms, by the accompanying state of the tongue, and by the general complexion of the disease. The features are drawn and dejected, the face flushed, and the forehead moist and clammy; the lips are red, the conjunctiva injected, and the eyes prominent. There is considerable thirst; the tongue is dry and parched, sometimes hard and scabrous; it is generally of a brick-red colour, or it is covered with a thin brownish mucous crust; sometimes it presents the appearance of raw flesh, and has been not inaptly compared to a beefsteak or cleanly dissected muscle. If crudities be present in the stomach, which is, however, seldom the case, or if a saburral be added to an inflammatory state of the mucous membranes, the root of the tongue is loaded with a yellowish white fur, whilst its point and edges are of a bright red colour, or the papillæ are prominent, projecting through the fur; the breath is fetid and the taste bitter. In this state only are there ever acid, nidorous, or fetid eructations. The throat is sore, the fauces are erythematous, and, together with the inside of the mouth, frequently become aphthous. Sometimes the tongue is of a dark red colour, resembling the lees of wine, occasionally as dark as logwood. This colour indicates the co-existence of congestion and plethora of the abdominal circulation. The bowels are constipated, but to this state diarrhoea is apt to succeed as the disease continues. The urine is high-coloured; the skin dry, harsh, and flaccid, except during sleep, or while digestion is in progress, when there are frequently heavy, partial, unsatisfactory sweats. The pulse is quick, hard, and small. In the evening and during sleep there is generally an exacerbation of all the symptoms, marked by agitation and restlessness.

There is also a more chronic form of this complaint, which either arises more gradually, or into which the states we have just been describing may have subsided. It is marked by great uncertainty of appetite, sometimes impaired, sometimes morbidly increased, a sensation of heat at the pit of the stomach, sometimes likened to the feeling of a burning coal placed there, or there is a distressing sensation of craving, sinking, or indescribable anxiety. The patient is generally much tormented with flatulence and the symptoms to which it gives rise, a sensation of choking, anxiety, restlessness, and hiccup; and he sometimes suffers much from pulsation at the præcordia, from spasmodic pains in the epigastric and left hypochondriac regions, or there may be a violent pain at the epigastrium extending through the

left hypochondrium and left shoulder; frequently there is a sense of heat internally when the surface is cold, not inaptly termed by the common people an *inward fever*. All the symptoms are much increased by taking food, even the mildest, so much so that patients are afraid of taking food on account of the uneasiness produced by it, from a feeling as if the stomach were incapable of holding anything beyond the smallest quantity. When the stomach is empty, some patients are entirely free from complaint. The bowels are costive, the urine scanty and high-coloured; the tongue is moist and clean, but redder than natural, generally broken by sulci and studded with large developed papillæ; sometimes it is covered with a thin, milky, white fur, through which the papillæ project; the gums are often red, swollen, and spongy, and there is often a taste of salt, of alkali, or of blood in the mouth; sometimes the tongue presents a dry and glazed appearance, with insatiable thirst, and a dry parched state of the mouth; sometimes there is a raw and tender state of the mouth and throat, with uneasiness in swallowing; or there is a sense of burning in the mouth and throat, with hysterical constriction, pain and soreness in the course of the œsophagus. The pulse is small and feeble, and quicker than natural; the skin is dry, rough, shrivelled, flaccid, and sometimes at length almost scaly; the nails become dry and brittle, and often curved; the hair is parched, and inclined to stand on end, and the whole surface is cold. The patient is constantly hanging over the fire, and frequently experiences fits of chilliness, approaching to shivering. The feet and hands are either preternaturally hot or cold; there is coldness or a cold torpor of the extremities, with a general sensation of chilliness; extreme morbid sensibility of any change of temperature, so that when the patient gets warm in bed he soon becomes hot and oppressed, the soles of his feet and palms of his hands burn, and he tosses about restless until he breaks out into a strong and heavy sweat. His sleep is interrupted and unrefreshing, and he awakes hot, thirsty, and weary, in a state of confusion of mind.

The ordinary accompaniments of this chronic affection of the mucous membrane of the stomach are great languor and depression, sometimes insupportable, the patient sinking into a state of extreme debility on the least exertion. The body is wan and emaciated, frequently sallow, the temper fretful, anxious, impatient, or dejected; sometimes there is a troublesome cough, dry, or with scanty mucous sputa; or there is dyspnoea, and pain of the chest like pleurisy; and in either case the symptomatic febrile affection approaches so near to hectic, that it is not rarely mistaken for consumption; sometimes there is palpitation and other irregular actions of the heart; sometimes headache, a tense binding pain across the head, vertigo, or tinnitus aurium; sometimes neuralgic pains of the limbs, sometimes osteocopic or painful affections of the periosteum; and

frequently some affection of the skin, chiefly *erysipelas*, *erythema*, *lichen*, *urticaria*, *pityriasis*, *psoriasis*, *alopæcia area*, the head becoming bald in round patches. But whatever be the most prominent secondary affections, the chief subject of the patient's complaint, there is a characteristic colouring common to every one of them,—they entirely engross his thoughts and occupy his attention, unless, which is not rarely the case, his bodily suffering be transformed into, and represented by, some mental hallucination. The patient's mind never turns from his sufferings, or if it does for an instant, it is only to revert to them with increased earnestness; and as the external senses constantly exercised acquire a fine and acute delicacy of sensation, so that they can take cognizance of minute and subtle objects which escape the ordinary sense, so the internal sense, painfully exercised in suffering which occupies his exclusive attention, acquires a keen microscopic power, and a fineness and subtlety of perception, which, surpassing common experience, is classed as partly nervous, partly imaginary, under the term of *hypochondriasis*,—a disease which M. Broussais satisfies himself with explaining as consisting in an excess of gastric susceptibility.

The change which takes place in the process of digestion is also a remarkable feature, which ought not to be omitted in the history of inflammatory dyspepsia. The food seldom runs into fermentation, acid or rancid eructations are rarely observed, and heartburn becomes comparatively rare; so that if the patient have previously suffered from atonic dyspepsia, he will observe that his heartburn has entirely left him. Certain kinds of food also are observed to be more easy of digestion, as farinaceous food, preparations of the fecula of vegetables, vegetable jellies, and mucilages, vegetable acids, and sweet diluents; the fat of meat, even the fat of bacon in moderate quantities, is more easily digested than lean, than animal jellies, than fibrous or albuminous substances, than eggs or milk.

The symptoms of inflammatory dyspepsia are invariably aggravated in spring, the period during which they are most severely felt being from the spring equinox to the summer solstice. They are also exasperated under the use of medicines of a stimulating quality, which can seldom be borne for more than a few days; and the same is observed of any strong purgative, which invariably gives rise to griping, irritation, and general exhaustion.

Causes.—Inflammatory dyspepsia is much influenced by age, sex, temperament, climate, and season. It is frequently met with in youth and early adolescence, but prevails most from the age of twenty to forty. It affects much more the male than the female sex, and chiefly the sanguine and bilious temperaments, people of a bright florid or of a dark complexion, but of a dry hard fibre. It is met with most frequently in hot and in dry climates, but more especially in those subject to an exces-

sive range of temperature. It is frequent in windy situations, in places exposed to dry winds, whether they be hot or cold. European Turkey, Greece, Italy, Spain, and the south-eastern parts of France, are places which unite all the foregoing conditions, for which reason this disease is also endemic in these countries. The Venetian Friuli was the country in which this disease seems first to have arrested the attention of M. Broussais, a country placed pre-eminently in the foregoing predicament. The late Dr. Parry, of Bath, has taken notice of the prevalence on the sea-coast of the morbid condition of the mucous membranes on which this disease depends, an observation which we have had frequent occasion of confirming at Nice, Genoa, Marseilles, and at Brighton, which may account for the indispositions, in common language, the *bilious attacks*, which many persons experience on coming to the sea-side; but we are disposed to think that the sea-air is not the only condition, for we do not recollect to have met with it much on the coast of Devonshire, where we have had equal opportunities of observing it. We must, therefore, limit the observation to the sea-coast in dry climates. Spring, as has been already observed, has great influence in calling forth and in aggravating the complaint: it returns also with the approach of cold in October. It occurs, however, at all seasons, in extremely hot or extremely cold weather, during sharp or long-continued frosts, during the prevalence of dry winds whether hot or cold; hence we find it to prevail in England during the north-east wind, in Provence during the *mistrale*, in Switzerland during the *bise*, and in Italy when the *tramontana* blows. It is met with in every rank of life, in the country as well as the city, in the outdoor peasant as well as in the artisan.

Certain states of body predispose to this disease,—as a state of general vascular plethora, a state of congestion of the abdominal circulation, suppression of the hemorrhoidal flux, suppression of the menstrual discharge, for which reason it is not uncommon in women at the critical term of life, to which we may add protracted atonic dyspepsia, the stomach becoming irritated by the habitual remora of crudities.*

But certain habits of life have the chief influence in inducing this complaint, such as living on dry, heating, and high-seasoned food, the habitual use of ardent spirits, of liqueurs, of punch, and of opium; hence it is the dyspepsia of the dram-drinker and opium-eater, and belongs altogether more to the drunkard than the glutton.

It may, however, independently of all predisposing circumstances, be at any time excited by certain accidental causes; as, for instance, by drinking cold liquids after violent exercise or fatigue, when the body has been cooled by perspiration, as frequently occurs in summer; by any unusual excess in diet or drink, more

especially if the body is in a state of exhaustion; by any accidental indigestion, as from eating mushrooms, cucumbers, some kinds of shell-fish, nuts, and such-like; by change of diet, from a succulent refreshing to a dry heating diet,* as our French and German friends frequently experience on first coming to dwell amongst us; by a change of water from a soft to a hard calcareous water; by fatiguing and forced journeys; by night-watching; and hence it occurs frequently in nurses, or those fatigued by long attention upon sick friends or relatives; by grief, anxiety, sad or depressing passions, or by sudden bursts of passion; by change of air from a heavy dull atmosphere to a clear dry sky, and hence it is, in connection with the influence of sea air, observed in a slight degree amongst our citizens during the first days of their visit to Brighton; by strong and stimulating medicines,† thus we have known it to follow the use of cubebs and copaiba given for gonorrhœa, of Fowler's arsenical solution given for affections of the skin, of strong and irritating purgatives, stomachic medicines, tonic tinctures and elixirs, and irritating vomits, as mustard. It occurs frequently under a course of mercury, when the constitutional action takes place quickly or runs high. It may also accompany catarrh, or be itself an effect of exposure to cold; it succeeds to the imperfect convalescence of gastric fevers, and supervenes on suppressed perspirations, and the repulsion of cutaneous eruptions.

Pathology.—That the form of dyspepsia we have just described proceeds immediately from vascular excitement of the mucous membrane of the stomach, it would be idle to set about proving. It would be superfluous to observe that no other hypothesis will account for the symptoms, or explain the operation of the causes of the disease, when the fact has been directly proved by innumerable dissections.

Whilst many of our predecessors have recognized and distinguished this particular form of disease, some of them have pointed out the morbid condition on which it depends. Thus, though Hippocrates has described it under a false name, he has yet set it apart as a particular form of repletion; whilst Celsus in its name has explained its nature—*stomachi ingens calor—ubi stomachus exestuat*. The Methodists knew the disease under the term of *passio stomachica strictura*, and by their method of cure we may see that they also understood its nature. It was afterwards accurately described by Ætius under the term of *stomachi adstrictio*,‡ and may, indeed, be traced down-

* Ariditate et erethismo ventriculi a defectu potûs aquosi.—*Sawages*.

* *Magis istam jugis indigestio parat.*—*Cæl. Aur.*

wards under various appellations in the writings of every succeeding physician. In Italy the knowledge of the disease, its nature and its cure, have been handed down by traditional experience, and is now safely deposited in the hands of the vulgar, within the reach and comprehension of every *baglia*. Not to cite unnecessary examples from modern physicians, Sauvages has, under several of his diseases of symptoms, described its form and indicated nature, for his *anorexia biliosa vel canicularis*, his *cardialgia inflammatoria a veneno et sputatoria*, his *pyrosis a phlogosi et Suecica*, and his *gastrodynia adstringens*, not to mention several others, are only so many symptoms of this disease. Under the term *gastritis erythematica* Cullen has recognised this disease, but the false principle of his nosology separated it from dyspepsia; and we can hardly recollect any instance in which false classification has been so detrimental to sound practice, or in which the influence of good and bad classification upon practice is more strikingly illustrated. From the time of Cullen to the time of Broussais, the symptoms of indigestion were considered purely a nervous disease, an adynamic affection, one of deficient vital power. For though Prost* in France, and Parry in England, had, the one by dissections, the other inferentially, arrived at the conclusion that dyspepsia or disordered digestion might arise from an increased vascularity, a morbid fulness of the vessels of the villous coat of the stomach, it was unquestionably the author of the *Histoire des Phlegmasies Chroniques* who led us back to the right point of observation, and who afforded us the means of recognising and distinguishing these affections. His view of the matter has been amply confirmed by succeeding physicians, even by those who have arrived at his conclusions by a different path, by W. Philip, Andral, Louis, Abercrombie, Cooke, not to mention many more. It is probable, that, had Parry not fallen into the error which obscures the merit of Broussais—that of considering this morbid condition as exclusively the proximate cause of every form of dyspepsia—he might have had more influence on the sober minds of his countrymen.

The vascular excitement of the mucous membrane of the stomach occurs in various degrees of intensity, from a state of mere dryness or defective secretion of the membrane, of injection, congestion, or morbid fulness of the vessels, from a state of erethism or increased action, to actual inflammation. And dissection reveals to us that the inflammation of the mucous membrane of the stomach, and so probably the erethism or vascular excitement which is not aggravated to inflammation, may present itself under three varieties; for it may affect the general substance of the mucous membrane, or it may be confined to the villousities which project from its surface, or the follicles which are imbedded in it,—in all

probability giving rise to diversities and modifications of the disease hereafter to be ascertained by closer and finer observation.

In the dyspepsia of the dram-drinker, marked by loss of appetite, by nausea and vomiting when the stomach is empty, and pain at the pit of the stomach, the stomach itself has often been found with a smooth glass-like surface internally, the extremities of the vessels in the villous membrane having been abraded or absorbed.

Inflammation of the mucous membrane of the stomach appears in many cases to commence in a very small and circumscribed portion; its progress seems to be very slow, and it is probable it may continue for a considerable time, and then subside, and again occur after various intervals, until at last it produces some permanent and extensive disease by thickening of the parietes of the stomach, by adhesion to the neighbouring parts, or by ulcerations.

Dr. Cullen observes, "Erythematic inflammations of the stomach are more frequent than those of the phlegmonic kind. It appears at least from dissections, that the stomach has often been affected with inflammation, when neither pain nor pyrexia had before given any notice of it; and such inflammation I apprehend to have been chiefly of the erythematic kind." "This affection of the stomach, viz. inflammation of the mucous membrane, sometimes spreads into the esophagus, and appears in the pharynx, as well as on the whole internal surface of the mouth." "When, therefore," he continues, "an erythematic inflammation affects the mouth and fauces, and when at the same time there shall be in the stomach an unusual sensibility to acrids, with a frequent vomiting, there can be little doubt of the stomach being affected with the same inflammation that has appeared in the fauces. Even when no inflammation appears in the fauces, yet if some degree of pain be left in the stomach, if there be a want of appetite, an anxiety, frequent vomiting, or an unusual sensibility with regard to acrids, some thirst and frequency of pulse, there will be then more room to suspect an erythematic inflammation of the stomach; and we have known such symptoms discover their cause more clearly by the appearance of the inflammation of the fauces or mouth." "The erythematic inflammation," he also observes, "is often disposed to spread from one place to another upon the same surface, and, in doing so, to leave the place it had first occupied. Thus such an inflammation has been known to spread superficially along the whole course of the alimentary canal, occasioning in the intestines diarrhoea, and in the stomach vomiting; the diarrhoea ceasing when the vomitings come on, or the vomitings upon the coming on of the diarrhoea." In the following passage Parry has made a corresponding observation. "In that state of tongue so common in the West Indies, in which the mucous membrane of that and the adjacent parts is affected with

* Prost, Sur la Sensibilité.

chronic inflammation, tending to aphthæ and suppuration, the stomach, apparently by mere extension of disease, suffers all the symptoms of flatus, acidity, &c. which are common to dyspepsia." Broussais has remarked that a contracted state of the stomach and alimentary canal always co-exists with an inflamed state of their mucous surfaces.

Inflammatory dyspepsia occurs frequently as a secondary as well as an idiopathic disease. Hence it appears as a symptom of some essential fevers,* of variola and rubeola, (dyspepsia febrilis); it occurs in the last stage of phthisis pulmonalis, and in many organic diseases; it is frequently symptomatic of inflammation of the mucous membrane of the uterus, particularly that which follows retention of a part of the placenta; it is observed in plethora of the uterine system, and in plethora of the abdominal circulation (*dyspepsia hemorrhoidalis*); and is met with consecutive to extensive burns, and cotemporary and reciprocally with erysipelas, erythema (*dyspepsia metastica*), and several cutaneous diseases; and we have several times found it co-existing with ichthyosis, and that dry impervious state which might be distinguished by the term of *constipation of the skin*.

Method of cure.—I. Instead of exercise, as in the former species, we must here seek for repose of every description,† of mind as well as of body; but as some exercise is desirable for the general health, it must be of the easiest kind, such as gentle sauntering, walking, or the passive exercises of gestation in a carriage, sailing, swinging, rocking, and gentle friction. Instead of a dry diet, consisting chiefly of animal food, we shall find that a liquid diet, bland and farinaceous, small in quantity at a time, from which animal food and all indigestible substances are excluded, is the most to be recommended. The different articles of food comprehended under the saccharine, acidulous, mucilaginous, farinaceous, and feculent, are most easily digested in this morbid condition of the stomach, and therefore their opposite kinds, milk, eggs, cheese, fish, animal food, animal gelatine, the substantial, solid, or fibrous parts of vegetables, and fruits, are to be abstained from. After repose, or rather diminution of labour and exercise, and a refrigerant diet suited in degree and kind to the particular state of the digestive organs, the warm bath may form part of the regimen. It should be used at a temperature from 92° to 96°, from a quarter to half an hour. If the symptoms require, it may be used every day; and it is of more benefit if used continuously, in a course of ten or twelve daily baths, than if taken interruptedly. Under this mode of administration, the tepid bath forms a direct remedy of great efficacy. But the general cure of this morbid condition of the stomach consists in a judicious use of the antiphlogistic

regimen, graduated to the degree of the disease and the strength of the patient.

In the lowest degree of this complaint a change of diet, avoiding stimulating and heating food and drink, abstaining from active exercise, the use of a tepid bath, of some cooling acidulated drink, as lemonade, orangeade, imperial, orgeat, preserving the bowels open by a simple warm-water clyster, and, if necessary, any mild cooling aperient, for which purpose none answers better than manna dissolved in infusion of tamarinds, to which a small dose of some neutral salt may be added, afford all that is requisite for the cure.

In a higher degree of this complaint it may be necessary to have recourse to a regimen more rigidly abstemious, consisting of gruel, arrow-root, whey, sago, blanc-manger of rice, jelly of bread, of Iceland or Irish moss, solution of gum tragacanth acidulated with lemon-juice, taken in small quantities at a time, in order to avoid distention; to prescribe largely acidulated saccharine drinks, as lemonade, cool, cold, or iced, or such bland drinks as orgeat, emulsions, decoction of liquorice, linseed-tea, &c.; to apply leeches or cupping-glasses freely to the epigastrium;* or, which is probably to be preferred, a moderate bleeding from the arm, proportionate to the degree of the disease: if there be signs of plethora or congestion of the abdominal circulation, leeches to the anus; to relieve the bowels by clysters or the mildest aperients, and to solicit the hepatic secretion by small doses of the pil. hydrarg. or pulv. hyd. cum creta given at bed-time, followed in the morning by small doses of castor-oil. The effects of mercurials must be assiduously watched; for in this disease they are apt to act locally on the mucous membrane, and thus affect the mouth, without, however, affecting the system at large. When mercurials are not used, the nitrate of potass may be given in repeated small doses; for this medicine, antimonials, castor-oil, hydrocyanic acid, the vegetable acids and saline medicines, are the means we are acquainted with which possess most eminently the direct power of lowering the vascular excitement of the stomach; and we do not hesitate sometimes to rely upon them in cases where venesection might otherwise be necessary. These means will be assisted, and their operation promoted, by the use of fomentations or emollient cataplasms to the abdomen, and by the daily use of the tepid bath. As the excitement subsides, the patient may gradually return to a better diet, beginning with light broths of veal or chicken, and at last, but more cautiously, solid food.

We are not unaware that the vascular excitement of the mucous membrane of one portion of the alimentary canal may be diminished by causing a determination to and a secretion from another part of it, and that thus the vascular excitement of the stomach may be reduced by a course of purging; but though this method

* In febribus circa ventriculum et fortis æstus et cordis morsus, malum.—*Hipp.*

† Omnifaria requies.—*Cæd. Aur.*

* Cucurbita adjuncta scarificatione, sive hirudinum appositio.—*Cæd. Aur.*

may be frequently successful, it is not rarely prejudicial, sometimes dangerous.

In the chronic form of the complaint great nicety is required in adjusting the cooling treatment to the strength of the patient and the degree of the disease; for if the disease has been of long continuance, the nervous system is generally affected, and tolerates with difficulty the means suited to the relief of the local complaint; and if the depressing means be disproportionate to the degree of the disease, the stomach sinks into the opposite state, atonic dyspepsia supervenes, and the method of treatment is disparaged. This last consequence is more especially apt to occur if the inflammatory have succeeded to the atonic form of dyspepsia. It is on this account necessary to be cautious in the change of diet, and in the gradual withdrawal of stimulus. It may be advisable to continue in moderate quantities, the use of such animal food as is easy of digestion, as light beef-tea or veal-broth, in small quantities at a time, so as to avoid distention, and, by the bye, solid animal food; if not followed by thirst, increased heat, or headach, they are always useful. If the patient have been accustomed to stimulants, they must not be all at once, but gradually withdrawn; for it is an unquestionable fact that a highly morbidly sensitive state of the stomach may be developed, and even a certain degree of inflammation of its mucous membrane may be exasperated, by leaving off an habitual stimulus. The exhibition of medicines and of other directly depressing means must be modified by the same caution. Leeches will be less seldom necessary. Seltzer water, whey, two-milk whey, and goat's whey, may be used as substitutes for the acidulated drinks. The nitrate of potass may be made to be more easily tolerated by the stomach by mixing it with infusion of hop, chamomile, or quassia, to which, if no heat be present, a little tinct. cort. aurant. or tinct. card. comp. or spirit. æth. nitric. may be added. Dr. W. Philip observes that its alterative effect is not impaired by this addition. Or the hydrocyanic acid may be combined with these instead of the nitrate of potass, if there be any painful affection of the stomach. The *vinum seminum colchici* in very small doses has also to a certain degree the same effect. We have also observed that a water-ice eaten very slowly in the evening, instead of tea, is attended with very good effects; and in summer we have known great benefit derived from swallowing slowly and at intervals small pieces of solid ice when the stomach is empty, which, if the stomach can bear it, proves both a tonic and refrigerant.

With this plan of medicinal treatment much advantage may be derived from a diet well-timed and tempered, always varying it a little: as, for instance, animal food at first only on alternate days, afterwards on two succeeding days, and so on, but now and then interposing a day of abstinence. The same observation is also applicable to medicines: a certain change

and variation of several is preferable to a long continuance of any one.

The bowels must be preserved open by the mildest and least irritating remedies. For this purpose clysters are to be preferred; they should consist of simple tepid water, from a pint to a quart, barley-water, gruel, linseed-tea, or such-like, or in smaller quantities with the addition of a little salt, honey, or electuary of senna; sometimes cold spring water is found to answer best. When aperients must be had recourse to, they should be bland and unirritating,—castor-oil, manna, soda with citric acid in effervescence, tartarised soda in infusion of tamarinds, confection of cassia or of senna. Ripe fruits eaten in the morning in considerable quantities have been found to have the effect of mild aperients, and to be at the same time refreshing to the stomach, such as ripe grapes, strawberries, and figs, which we believe to be the full meaning of the *cure des raisins* so much spoken of in Switzerland; but this method requires considerable caution, for if the fruit be not digested, the object is more than frustrated.

In the chronic state of the disease it is generally necessary to promote the secretions of the liver and alimentary canal by very small alterative doses of mild mercurial medicines. They afford valuable assistance to the general principle of treatment; but we must not forget the readiness with which they are apt to affect the mouth. Neither should the morbid condition of the skin which obtains in the chronic form of this disease be allowed to escape the attention of the physician in combining his method of treatment. He should seek not only to relieve its dry, impervious, constipated state by tepid bathing, particularly the tepid sea bath, but he will find it a means of relieving the vascular excitement of the stomach to produce a derivation to the surface by small doses of antimonials, either combined with a little liquor. acet. ammoniac, or with the nitrate of potass, or by giving alone a grain of James's powder every night at bed-time, or the tenth of a grain of tartar emetic three times a day. If much irritability be present, the hyosciamus is usefully combined with the antimonial. The following formula is well adapted to this intention:—*R* Tr. hyosciam. *m* xii. tr. opii. *m* ii. vel. iii. vini ipecac. *m* xx. potassæ nitratis gr. v. aq. flor. aurant. \mathfrak{z} i. fiat haustus h. s. sumendus. The determination to the skin may also in some cases be usefully promoted by the vapour-bath, and by moistening the skin every morning with a lotion of nitro-muriatic acid. The ancients appear to have had this object in view when they recommended the patient to be enveloped in woollen cloths impregnated with sulphur, and in directing friction to be made with nitre and oil.

But we must confess that in the protracted form of this complaint we have observed every object of this method of treatment fulfilled, and all medicinal means far surpassed in efficacy, by a course of mineral waters, such as those of Harrogate at home, and those of

Ems, Vichy, Plombières, and Caunterès abroad. To any of these, however, we should prefer the Kreutzbrunnen of Marienbad. Under its use we have often seen the tongue get cool, clean, smooth, and moist; the irritated papillæ subside; the uneasy sensations at the stomach give way; the skin become soft, smooth, and permeable; the bowels regular; and the healthy function of digestion entirely restored. It should be taken gradually and in small quantities, in repeated doses of three ounces each. It may be taken warm or cold, as most agreeable to the stomach; if it produce distention, the gas should be allowed to escape; if spasm or diarrhœa, it may be diluted with the Kesselbrunnen of Ems.

The same effect is sometimes obtained from a course of goat's whey, taken in considerable quantities in the morning after the manner of a mineral water, a practice which is followed in Wales, and in the highlands of Scotland, but more particularly at Geiss in Switzerland, with the greatest success.

Neither in the acute nor the chronic form of this complaint does our experience lead us to place much confidence in counter-irritants, and we think we have not rarely seen the complaint exasperated under their use. But many physicians, whose opinions deserve the highest consideration, place considerable reliance upon them. They consist of blisters, the tartar emetic ointment, and issues. In the chronic form of the complaint we have certainly known great relief to attend the wearing a large warm plaster over the surface of the stomach, and in very protracted cases we consider it a good preservative from a relapse, from spasmodic pains, &c.

M. Broussais, having observed the frequency of this complaint in the south of Europe, has mentioned a change to a colder climate amongst his means of cure; but our own experience is in favour of a soft climate, if not too cold. In this complaint we have known one season in Devonshire of considerable benefit; on the continent, the climates of Pau in the south west of France, Rome, and Pisa, are chiefly to be preferred. In the harsh, dry, impervious state of the skin, which takes place in the protracted state of this complaint, it is of great service to have an atmosphere and temperature soft, mild, and equable; and this consideration should also suggest the propriety of warm clothing, of rooms of equal temperature, and the occasional use of the tepid bath.

We think it unnecessary to enter into particular directions for mitigating or relieving the painful and distressing symptoms which are occasionally present in this disease, such as vomiting, pyrosis, gastrodynia, flatulence, and the various uneasy sensations felt in the region of the stomach. Their specific treatment is comprehended in the general method of cure; and for the secondary affections which originate in this morbid condition of the stomach, we can safely refer to the separate articles under which each of them will be considered as symptomatic diseases.

II. For the means of preventing the returning of this complaint, and correcting the predisposition of body on which it depends, we beg to refer to our plan of prevention in atonic gastric dyspepsia. With some modifications in the degree of the means suitable to the particular nature of this complaint, it will be found also to be of useful application here, after the morbid condition of the mucous membrane of the stomach has completely subsided.

III.—Irritable gastric dyspepsia.

Synonyms.—*Ἡ στομαχική, Aretæus; καρδιακή διάθεσις, Auct. Græc.*; cardialgia sputatoria; pyrosis vulgaris et a conceptione; gastrodynia atterens, hysterica, periodynia, et a frigore; vomitus nephriticus et hystericus; anorexia melancholica; flatulencia hypochondriaca, *Savvæg.*; anorexia ex desuetudine verneris, *Galen*; gastralgie, *French*; pain of stomach, most felt when it is full, *Pemberton*.

General character.—Pain, uneasiness, uncomfortable or unnatural sensations in the stomach, generally increased on taking food, and during the process of digestion, neither the frequency of the pulse, nor the heat of the surface being at the same time sensibly increased; the pain rather relieved than increased by moderate pressure; appetite variable, seldom much impaired; bowels constipated; stools little altered; urine clear and sufficiently copious; micturition frequent; tongue clean or thinly furred, never thickly coated; temper impatient, restless, and changeable; easily dejected, easily excited; the attention constantly and exclusively fixed upon the uneasy sensations; great variability in the degree and duration of all the symptoms.

Form of disease.—In the slighter degree or earlier stage of this complaint, when the stomach is empty the patient is comparatively free from uneasiness, but on taking food or in the course of digestion various uncomfortable sensations are wont to arise. The patient may feel a sense of choking or constriction in the stomach, as if the progress of the food had been arrested; the throat feels dry, so that it requires an unusual effort to swallow each succeeding mouthful, and after the food has passed down he is disposed frequently to repeat the act of swallowing, as if to relieve the uneasy sensation; without thirst, he continues to sip small quantities of liquid from the same instinctive feeling, or the same sensation leads him to be constantly hawking and spitting, as if he had some foreign substance in the throat. This is sometimes accompanied with dull, indistinct, but anxious pains in the back, between the scapulae, where the patient rubs or strikes himself, or requests some by-stander to hit the seat of the pain, hoping to be relieved thereby. In an aggravated degree the sensation in the stomach amounts to a severe constringing pain, and is attended with nausea, which, extending up the œsophagus, is met by a sensation of very painful constriction and stiffness of the lower jaw, chiefly in the situation of the parotid and submaxillary glands, followed by a copious discharge of a saltish saliva, which generally

affords relief; or all these symptoms are relieved by vomiting, the food being returned very little changed in its appearance, though frequently an hour has expired from the time of taking it: these symptoms together constitute *pyrosis*. Or, instead of constriction, a sensation of heaving or nausea follows the taking of food, which is also occasionally terminated by vomiting. Sometimes it is a sensation of heat or burning, of coldness, sometimes of itching, tickling, or formication; sometimes there is pulsation at the epigastrium, in the hypochondria or abdomen, appearing suddenly, at first violent, and abating gradually, observed by Schmidtman* to be synchronous neither with the pulsation of the heart nor arteries, and occasionally changing place suddenly, even sometimes transferring itself to the extremities. These symptoms are usually accompanied by various degrees of general irritation, by a state of fidgetiness, of restlessness, inquietude, or anxiety. Sometimes the uneasiness is not perceived in, or referred to, the stomach, but is felt sympathetically in some other part of the body. Thus, the patient may complain of a sense of tension, of painful anxiety in the head, or of an acute pungent pain limited to one spot; or the heart may be the seat of similar affections accompanied with palpitation or irregular action, seldom with stronger impulse, with flushing of the face, or quickness of the pulse; or the patient may be seized with fits of hard loud coughing, with convulsive asthma, or spasmodic affections of the muscles of respiration; with cramp of the limbs, spasmodic pain in the uterus, bladder, or urethra; or neuralgic pain in some part of the body, in the uterus, testicles, or rectum; frequently a fit of hysteria, sometimes even symptoms of hysteria in men. Or the patients may feel restless or unquiet, or be seized with a fit of depression, of ungovernable impatience or anxiety. These symptoms generally terminate with digestion, but may be renewed by taking the mildest food. They are usually accompanied with coldness of the extremities, and early in the attack a discharge of pale limpid urine takes place. The tongue is seldom furred, more usually clean, or it is covered with a thin mucous fur, interrupted by fine waving transverse lines; under actual irritation it is dry without being accompanied by thirst; more generally there is a deficiency of saliva, but the tongue and lips are covered with a white frothy secretion which the patient is ever endeavouring to get rid of by spitting; sometimes it is moist, and the mouth is filled by an unusual flow of saliva; frequently the tongue is thinly furred, as if a fine white gauze were thrown over it; sometimes it is covered with a thin milky white fur, as if the patient had just been drinking milk, and sometimes it is besmeared with a thin frothy mucus. The tongue is generally rather paler than natural, but even

when clean is never of a brighter red colour than in health. It is generally of a dull red, sometimes darker than natural. But the surface of the tongue, whether furred or not, presents the appearance of plush or velvet, which arises from the papillæ being fine and elongated, never either large, tuberosus, and developed, or smooth and obliterated. The bowels are usually costive. The pulse is generally small, feeble, and soft, or small and contracted; it is seldom accelerated, more frequently slower than natural, except under some temporary excitement or agitation, when it is momentarily hurried or irregular. The skin is generally soft, rather glossy, but never dry, harsh, and scaly, as in inflammatory dyspepsia; it is permeable but seldom moist, except sometimes from a sudden breaking out of perspiration on particular parts of the body; perspiration is rather suppressed than obstructed.

In the more protracted forms of this complaint the stomach is rarely free from uneasiness or discomfort of one kind or another; the patient is never unconscious of sensations in the stomach, and to whatever object his attention may be directed, the uneasy feelings of the stomach are mingled in all his perceptions, tinge and darken all his thoughts, thus giving rise to another form of hypochondriasis. These sensations are sometimes that of burning heat, sometimes of icy cold, sometimes of gnawing, grinding, or dragging of the stomach, or of some foreign substance in the stomach, sometimes of emptiness or hollowness, of falling or sinking of the stomach, sometimes of nausea; or there is a constant sense of rising in the throat, sometimes of a round ball, sometimes of an insipid liquid. These uneasy feelings completely take away all power both of mind and body; the spirits become dejected, the body torpid, the limbs powerless,* the mind is prostrate, exclusively fixed upon the uneasy bodily sensation, or ever contemplating the gloomy association or the dark course of thoughts which they call forth;† and the sensibility of the stomach becomes consequently so highly exalted, that patients refer to it all their sensations, as is well expressed in a letter to Pinel from a lady, one of his patients: “Le principe de tous mes maux est dans mon ventre; il est tellement sensible, que peine, douleur, plaisir, en un mot toute espèce d'affections morales, ont là leur principe. Un simple regard désobligeant me blesse cette partie si sensiblement, que toute la machine en est ébranlée. Je pense par le ventre, si je puis m'exprimer ainsi.” Or there may be a feeling of anxiety, of restlessness, or impatience, which can neither be controlled nor overcome, with great nervous susceptibility; the mind is much impaired; the senses become delicate, and the head giddy, the eye

† Ἰσχυροὶ, ἐξαχχοί, ἀσθενεῖς, ἐκλυτοί, λειποδρανεῖς, ἀφυχοί, δεῖλοι, ἡτύχοι, ἐξαπίνης δ' ὀργήλοι, κάρτα μεταλλοχολιδεῖς. — Aretæus.

dazzled by the least effort of attention. Sometimes this morbid irritability is most apparent in the vascular system, the pulse being quickened, the heart made to palpitate, the face to flush with a sound of rushing or ringing in the ears. This peculiarity seems frequently to arise from excessive loss of blood. Urticaria, prurigo, stinging or itching of the skin, are not unusual attendants.

These symptoms are occasionally for a time relieved by taking food, and only return as the stomach becomes empty, which acquires a painfully irritable state as the period of taking food is delayed, but they are more commonly aggravated during the process of digestion; and sometimes, in a higher degree of gastric sensibility, severe pain is excited by swallowing the smallest morsel, which is on some occasions instantly rejected. In some cases liquids produce greater uneasiness than solids, and sometimes medicines are the greatest irritants. The symptoms are very much aggravated by purgatives; flatulence, violent palpitations, with a sensation of approaching syncope, and vertiginous feelings in the head, have been observed to arise upon the action of the mildest purgatives; sometimes violent diarrhoea follows the action of a moderate aperient. The pain and uneasy sensations at the stomach are frequently relieved, but sometimes inordinately increased by touch or pressure upon the epigastrium.

In this complaint there is great uncertainty or variability of appetite; sometimes inappetency, even disgust for food, in its most aggravated form; frequently capriciousness, not rarely craving for food; remarkable antipathies and likings for particular kinds of food are frequently observed, and sometimes sudden fits of voraciousness, for such persons generally eat their meals very quickly. There is seldom thirst, but frequently a feeling of dryness in the throat and fauces. The bowels are universally confined, but the fecal evacuation is little altered in quality. The urine is abundant and pale-coloured, and frequently occasions smarting in its passage, its specific gravity being considerable and the urea abundant. The sleep is variable, but seldom refreshing;* patients in this disease are easily put off their sleep; they either sleep heavily, or have difficulty in getting to sleep; if the mind be in the least degree excited or occupied, they pass a wakeful night, the mind being thrown into a state of erethism which they cannot quiet.

Complication of irritable and inflammatory gastric dyspepsia.—When irritable gastric dyspepsia has been of long continuance, when stimulating or irritating remedies have been used for its cure, either heating, stomachic, and antispasmodic medicines, or strong and irritating purgatives, or if the patient have been led by his uneasy sensations into the habit of taking small quantities of ardent spirits or opium, an inflammatory state of the mucous membranes is apt to be superadded to the morbid sensibility and irritability of the stomach, and thus

is formed the most difficult and obstinate form of the disease with which a physician has to contend. The symptoms of both diseases are mixed up together, forming a combination very difficult to unravel, a difficulty much increased by the conflicting evidence which the *juvantia* and *ludentia* afford. The tongue affords the most distinct indication; it is red along its margin, frequently having round spots or points of a darker red interspersed; it is little furred, or has a brownish slimy fur; small ulcerations occur upon the tongue, as likewise upon the inside of the mouth. This appearance, united with symptoms of great nervous irritability, always indicates the combination of both morbid conditions.

Causes.—The circumstances capable of inducing irritable dyspepsia are, either such as act directly or locally upon the stomach, or such as influence the stomach indirectly by acting upon the general system, but the coincidence of causes belonging to both these classes, has the most powerful influence in determining irritable gastric dyspepsia.

To the first description belong the habitual remora of crudities in the stomach, and therefore, in certain temperaments and under the modifying influence of more general causes, irritable not rarely succeeds to atonic dyspepsia; living upon hard, poor, and indigestible kinds of food, not suited to the nature of the body. From this cause proceeds the dyspepsia which afflicts the Irish poor, a great portion of whom live entirely on the potatoe, without milk, butter, or any kind of condiment; and many of the peasants of Scotland, highland and lowland, too strictly confined to the oaten bread; which accounts for the prevalence of pyrosis in these countries; and to a deficiency of quantity and an unnatural quality of food is no doubt owing much of the dyspepsia of the poor in large cities, where it has been known that families have subsisted for a time on the rind of potatoes, and every description of poor and loathsome food;* men in the centre of civilization experiencing all the uncertainty of subsistence which belongs to savage life, without the habits which give them strength to sustain it. Other causes are, change from a stimulating, nutritious diet, to one of a poor cold nature; leaving off any accustomed stimulus, as opium; a certain tenderness (*teneritudo*), delicacy, or partial irritability of the stomach, sometimes inherited, but also the consequence of over care and restriction in the choice of food;† abstinence and prolonged fasts, hence dyspepsia is a frequent consequence of the strict observance of the Catholic fasts, and hence Pinel numbers among the causes of dyspepsia the abstinence of the Bramins, of the Fakirs, and

* *Ευνήδες δὲ καὶ τοῖς ὑπὸ τε ἀνδραγαθίας ἐκδεδητημένοις λεπτῇ καὶ σκληροτέρῃ διαίτῃ.*—Aretaeus.

† Multi ceteroquin sani et robusti parèe atque timide cibum sumunt ob metum ne in cruditate et exinde morbos delabunt cum ob illum ipsum timorem et vanam imaginationem non solum exiguum illum cibum malè digerunt sed ob hoc in morbos incidunt.—Baglivì.

* Οὐχ ὕπνου ἀτρεκέϊ.—Aretaeus.

the ancient anchorites of the Thebaid. Certain acrid and irritating ingesta, as the habitual use of mercurial preparations, sometimes irritating purgatives, very strong green tea, and such like.

The causes of the second description are a delicate, irritable, nervous temperament, hereditary or acquired; irritability of mind, usually the consequence of moral causes, as of anxiety, vexation, envy, jealousy, nostalgia, contrarities, reverses of fortune, over-indulgence in tender feelings, nourishing a delicate sensibility, and avoiding too carefully the ordinary rubs of life. Baglivi says, "*Patres familiaris et rei familiaris curâ distenti aut in dignitate fuerint constituti, aut in aulâ vivant.*" He might also have added the mothers of families, for we are not acquainted with a more general cause of this disease than the anxieties of mothers watching over the health and education of their children, their own health at the same time being frequently undermined by diseases peculiar to their sex. We may add causes which disturb, extremely exhaust, or debilitate the body, as concussion of the brain, repeated venesections inopportunistically employed; protracted and exhausting hemorrhages, weakening discharges; all which causes are more powerfully felt if the stomach be irritated by indigestible food or exciting physic; climates and season of year, frequent and sudden variations of temperature, to which probably may be attributed the colic of Madrid, nearly related to this disease, and also the prevalence of this disease in the spring in our own country.

The morbid irritability of the stomach may be also sympathetically induced from its consent with other organs. This affords a common source of the disease in the female sex, in whom it is often induced by an irritable or painful state of the womb, as occurs in dysmenorrhœa, in some forms of menorrhagia, in leucorrhœa, pregnancy, lactation, and hysteria. But the same effects may follow an irritable or painful performance of the function of other organs, as is exemplified in a painful state of the kidneys and ureters, in stricture of the urethra, in an irritable state of the testicles, and in other painful local complaints.

Pathology.—Though the ancients did not generalize the phenomena of this disease under any specific term, they have most accurately described them. Hippocrates has detailed the symptoms in his account of that state of body which the fatigue exceeds the support,—*οἱ πόνος κρατέουσι τῶν σίτων*, and we doubt much whether a more faithful portrait of it is to be found than that left us by Aretæus of his disease—*στομαχικῇ*. The Methodists would seem to have known it under the term *durities stomachi*, a sub-species of their *passio stomachica strictura*. It was very fully described and treated of by Cheyne, was noticed by Tissot, Pommé, and other writers, but most especially by Whytt, who was himself a sufferer from it. The nature of it was very clearly pointed out by Pemberton under the term of "*pain of the stomach increased upon taking food*," as will appear from his own explanation. "The pain

of the stomach, which is most felt when it is full, would appear to arise from irritability of the muscular coat of that organ, and not to be at all connected with the glandular secretions of it; for unless the pain be called forth by taking food, it will rest perfectly at ease. This disease seems particularly to attack chlorotic women and hypochondriacal men; I am, therefore, inclined to believe that it owes its origin to the muscular fibres of the stomach partaking of the general irritability of all muscular parts in an irritable habit; and I think that the advantage derived from the method of treatment hereafter mentioned will add considerable strength to this opinion." In Germany it was very accurately treated of by Schmidtman under the name of one of its symptoms, *cardialgia*,* by which is understood any pain or uneasiness of the stomach, not heartburn, as it is usually translated; in France by Louyer Villermay under that of hypochondriasis, which he considers to depend upon some modification of the organic sensibility of the abdominal viscera, especially of the stomach; and was, lastly, more fully developed by Barras,† he himself having experienced the disease to a deplorable degree. We are indebted to Dr. James Johnson for having recalled the attention of the profession in England to this disease in his able work on the morbid sensibility of the stomach.

They who are practically conversant with the sufferings of the human body, are too well aware that it does, under certain circumstances, assume a morbid condition which supports with difficulty the impressions of all external agents, even the most ordinary, whether their property be to excite, to depress, or otherwise modify the vital powers. This state of body perceives impressions, in kind and degree, not cognizable in the healthy state of sensation, and is excited to action by slight causes, which in the ordinary state of health would have no effect. Persons labouring under this affection are disturbed beyond all measure by the weakest stimulants, and are overwhelmed by a sedative of the lowest powers. In such persons we have known a few grains of nitre to cause fainting, or a severe fit of colic, the loss of a trifling quantity of blood to induce a convulsion, a Plummer's pill to bring on deadly cold sweats, inexpressible agony, and all the threatening symptoms of instant death, a few drops of laudanum to induce convulsive fits and delirium. The phenomena of this morbid state of body have been generalized under the term *irritability*, consisting, as is evident, not only in a morbid sensibility, but also in a morbid susceptibility, or mobility, in some respects the reverse of that of atony, in which both the sensibility and mobility of the body are remarkably diminished, sometimes requiring the most powerful stimulus to call them into action; but both appear in some measure to be connected with a state of

* Op. cit.

† Traité sur les galgries de Paris, 1827.

deficient vital power, from the manner in which they are aggravated, if not produced, by debility and debilitating causes. In this respect, perhaps, their common nature might be acknowledged, whilst their particular character was distinguished, and thus atony might be termed passive debility, debility in repose,—irritability, active debility, debility in action.

This constitution of body may be hereditary or it may be acquired, but the manner in which it is engendered, though well deserving of investigation, has not yet been satisfactorily explained. It seems, however, capable of being produced in the strongest bodies by painful suffering or long-continued strain of body or mind. A painfully sensitive state of any part of the body, permanent or frequently recurring, by which as it were the nervous system is sustained in a constant state of erethism or wakefulness, and by which a second or morbid sensorium becomes by degrees developed, where every sensation is felt or reflected, seems to have the power of inducing this condition of body. The tic douloureux, calculus of the kidneys or bladder, stricture of the urethra, painful menstruation, chronic rheumatism, prurigo, even such insignificant ailments as tooth-ach or painful corns, afford every-day examples of this power. Painful gestation, difficult parturition, afford similar examples, but sometimes rendered more remarkably striking when combined with debilitating causes, as they frequently are, particularly by excessive losses of blood, as in flooding after miscarriages or lying in. But debilitating causes without pain have much less power in inducing this state of body. The most complete anæmia may sometimes be observed without irritability, and we fancy it will be found that the debility has been in the one case induced with pain, and in the other without it. Pain, however, supervening upon a state of debility, affords the combination of circumstances the most powerful in inducing irritability.

In the same manner the affections of the mind most capable of inducing this state of body, are long-continued care and anxiety, expectations deferred, and repeated disappointments, all the feelings usually comprehended under the term vexation, the effects of which, if examined into, will be found to consist in a state of painful consciousness, exactly corresponding to the state of body just described, both agreeing in exciting a constant and continued state of nervous erethism, and in developing a new seat of sensorial power, distinct from that of the common sensorium.

This view of the manner in which irritability is acquired, is amply borne out by the nature of the operation of the causes which are capable of exciting it, whether general or local, to both of which we must refer.

According to the operation of these two kinds of causes, this morbid condition may be general, affecting every organ of the body or it may be local, confining itself to some particular system or to some particular or-

gan. It may commence in some particular organ, and thence propagate itself to the general system, or it may, emanating from the general system, diffuse its influence over the whole body, or, from certain local causes, be concentrated upon particular organs. Instances of the former are afforded by the eye, which sometimes acquires a morbid degree of irritability out of all proportion to the general state. The same may be observed of the womb in painful menstruation, or after frequent miscarriages; of the bladder, which sometimes, without any inflammation, acquires a degree of irritability, rendering it incapable of retaining the smallest quantity of urine; of the urethra, giving rise to painful and spasmodic stricture; and the testes and kidneys, equally susceptible of this state, afford similar examples. The heart and vascular system appear also, from the influence of particular causes, to be sometimes placed exclusively under the influence of this state, as is shewn by the quick, irregular, and easily excitable pulse, the palpitation and disturbed action of the heart, the sudden flushing sometimes of the whole surface, sometimes confined to a small extent. It is not, therefore, to be doubted that the stomach and bowels may be affected in the same manner, and placed in the same morbid condition, consequently giving rise to a corresponding form of dyspepsia.

Nor is it difficult to understand either, how from local causes this state of morbid irritability should be engendered in the stomach, or how any disorder of the digestive function, when the constitution or any particular organ is under the influence of this state of irritability, should, by virtue of the law of consent, assume the form of disease.

When from any cause, as from habitual indigestion, the stomach is kept continually in a state of irritation or erethism by the remora of crudities, it becomes a seat of conscious sensation, to which the attention is continually directed. In consequence of which, as we have already explained, the stomach acquires an acute degree of sensibility like any other sense long exercised under the constant effort of the attention. To use the words of M. Barras, “la sensibilité de l'estomac s'exalte à un point étonnant; d'organique elle devient animale, pour me servir du langage de Bichât. Tout ce qui se passoit dans le principal organe de la digestion, je le sentois comme s'il se fut passé sur l'organe du tact, la présence des alimens y étoit perçue, comme elle auroit été sur la main.” That such is the effect of the remora of crudities we have a strong proof in the parallel case where foreign bodies are lodged in the stomach,* or generated there, as in the case of bezoartic concretions,† or parasitic animals.‡ In all these cases the same

* *Gastrodynia a peregrinis.*

† *Gastrodynia Calculosa, vomitus bezoarticus.—Sawages.*

‡ *Dyspepsia verminosa Cardialgia verminosa, vomitus verminosus, nausea à tania.—Id.*

morbid irritability is developed, giving rise to all the peculiar symptoms which belong to irritable gastric dyspepsia. The following case affords a good illustration. "A man of sixty years of age had for a long time experienced, whenever he took a little nourishment, violent cramps of the stomach, accompanied with a sensation of burning heat in that organ, and with the eructation of liquid so acrid that it ulcerated the pharynx and corroded the enamel of the teeth; to these symptoms were added vomiting, which returned several times in the day, a continual sensation of pressure and of agony at the præcordial region, disgust for food, habitual constipation, almost entire loss of sleep, and at last gradual wasting. One day, in one of his usual efforts of vomiting, a calculus was ejected, which afforded the patient some relief, and the day after a return of the vomiting effected the expulsion of a second. The first of these calculi weighed a drachm, the second half a drachm. A short time after these were ejected, the patient was restored to health."* Similar cases with corresponding results are also to be met with from organic causes, as, for instance, when tumours, fungous, vegetative productions have been found projecting into the stomach, they have been always preceded by the symptoms of irritable dyspepsia; ulcers of the mucous membrane of the stomach, and diminished capacity of this organ, have also been known to give rise to similar symptoms. And to this manner of operation may also be referred all the other local causes of irritable dyspepsia.

Of the secondary origin of irritable gastric dyspepsia, where the disorder of digestion emanates from, or is modified by the irritable state of the constitution, or of some other organ, we have examples of the former kind in concussion of the brain, in nostalgia, in the *cardialgia lactantium*, *anorexia cachectorum*, and *anorexia melancholica* of Sauvages; in the *anorexia exhaustorum*, *dyspepsia cachectica* of Cullen; and of the latter, in the *nausea nephritica*, *vomitum nephriticum*, in the *gastrodynia hysterica* and *chlorotica*, the *nausea* and *vomitum gravidarum*, the *pyrosis a conceptione*, of Sauvages; and in the *dyspepsia nephritica*, *hysterica*, *catamenialis*, *dysmenorrhœa*, *gravidarum*, *chlorotica*, and *hypochondriaca*, of Cullen.

We must also notice in this place a form of secondary dyspepsia arising from spinal irritation, which has been particularly described by Mr. Teale, of Leeds, in his very able and practical work on neuralgia. There can be no doubt that every species of dyspepsia may originate in a morbid state of the spinal marrow; but according to this writer the spinal irritation will be always perceptible on pressing some of the middle or lower dorsal vertebræ, or by tenderness in the neighbourhood of the middle and lower thoracic ganglia. This affords the chief distinction of this variety of dyspepsia, which, with the other secondary forms of dyspepsia, only derives per-

manent relief by the treatment of the primary disease.

Treatment.—The method of cure which experience sanctions is in exact correspondence with the pathological explanation which we have given of the disease. It consists of the following indications—viz. 1, endeavouring to render the function of digestion easy of performance by a selection of food suited to the nature of the disease; 2, correcting the morbid condition of the stomach, either *directly*, by the use of medicines which have the power of modifying its innervation, of diminishing its morbid sensibility and irritability; or *indirectly*, by such means as soothe and assuage the irritability of the whole body; and 3, by restoring the tone of the stomach and of the whole system, by which the morbid condition is not only removed, but its return prevented.

1. The first indication will be fulfilled by a proper regulation of the diet, suited to the sensibility of the stomach, and apportioned to the wants of the body, adjusting it to the exercise of the body and the occupation of the mind.

It may be collected from what has been said, that the waste outruns the supply, that the wear and tear of the body and mind exceeds the ratio of supply; but it would be in vain to think of restoring the equilibrium by increasing the quality or quantity of the nourishment, for the stomach could neither bear it nor appropriate it. It is therefore to be adjusted by diminishing the fatigue of body or the wear of the mind, as either may be the offending habit.

The chief object to be held in view in selecting the diet, is, that it should be of such a nature and in such a quantity as may be digested with the least labour and the least irritation, and such as leaves no indigestible refuse to gall and fret the stomach, thus keeping its sensibility ever awake. What answers this purpose best is a mixed diet, what Cheyne was used to call a *trimming diet*. It consists partly of animal and partly of farinaceous food, neither entirely dry nor entirely fluid or pultaceous, avoiding all those kinds which have been already specified under the treatment of atonic gastric dyspepsia, as universally indigestible. The quantity is also of paramount importance. The meals, of whatever they consist, ought to be very small, but may in proportion be more frequently repeated, it being of the first importance to avoid distention of the stomach. Some of the most aggravated forms of this complaint appear to have been cured by carrying this principle to its full extent. The cases related by Dr. William Hunter* and by Mr. Hey of Leeds were cured by feeding the patients on skimmed milk, given in very minute quantities, one or two table-spoonfuls at a time; and another similar case† was treated successfully by Dr. Barlow of Bath, by restricting his patient to a diet consisting wholly of fresh-made uncompressed curd, of which she took

* Andral, Anat. Path. p. 168.

* Medical Observations and Inquiries, vol. vi.

† Abercrombie, Diseases of the Abdomen, p. 51.

only one tablespoonful at a time, repeating it as often as she found it advisable. And we have known a similar case in which a preparation of the fecula of oats, known in Scotland by the name of *sowens*, in Ireland by that of *flummery*, given in repeated small quantities, proved equally efficacious: milk has been also used in the same way. Such a plan of diet refers, of course, to extreme cases. We have only mentioned these instances for the sake of impressing the importance of small meals. We have found the strictly dry diet invariably difficult of digestion, and would in general recommend to begin dinner by a few spoonfuls of light plain refreshing soup. A very small quantity of properly dressed tender vegetables is admissible. One glass of sherry, or two of claret, Sauterne, hermitage, or hock, or a proportional quantity of brandy and water, may be permitted, or these may be taken alternately with a small quantity of home-brewed beer. The temperature of the diet has also been found of very great consequence. It has sometimes been found that the food eaten perfectly cold has digested easily, when the hot has been immediately rejected, though the reverse is generally the case. It is of the greatest importance in every form of dyspepsia, but most especially in this, to eat deliberately, and to masticate the food with scrupulous care.

Procuring easy and satisfactory relief of the bowels is another means of indirectly relieving the irritability of the stomach. This object ought to be attained by the mildest means, for purgatives frequently disagree, and the milder purgatives act better than the rough or violent ones. When the simple clyster will effect this purpose, it is to be preferred: if not, some mild aloetic pill, similar to the formula already given, or the decoct. aloes comp. are the most suitable. It is sometimes of service to combine the extract of hyoscyamus, sometimes a minute quantity of opium, sometimes the sulphate of quina, and sometimes bismuth or steel, with the aperient.

Fatigue of body is sedulously to be avoided, and when the condition of life imposes labour, it is to be lightened as much as possible. Even for those with whom labour is voluntary, much exercise in this disease is not found advantageous, though dwelling as much as possible in the open air is always to be desired. The exercise should be easy, sauntering, soothing, and amusing, as slow moderate walking upon plain ground, exercise on horseback, or an easy-paced poney, driving in an easy open carriage, boat-sailing, or a sea voyage, if the season permit. Some light amusing game may be added to the exercise, as golf.

2. Some medicines have the power of acting directly upon the nerves of the stomach, and in that way of diminishing their irritability. One of the most powerful of these is the hydrocyanic acid, either as it is prepared, or as it is found in the distilled laurel water. The same power is also possessed by the extract of belladonna, and the nux vomica is used by the peasants of Lapland for their endemic pyrosis. The subnitrate of bismuth, the sulphate of iron, the arsenical solution, and the nitrate of silver,

are also remedies of the same nature, and have been attended sometimes with surprising effects. Camphor, valerian, and the fetid gums, are similar remedies of weaker powers. Their preparations, however, afford useful media for the exhibition of the more powerful medicines. If these medicines do not soon afford some mitigation of the symptoms, they ought to be discontinued. Alkali or alkaline mineral waters have considerable power in soothing the irritation of the stomach, as the liquor potassæ or lime-water, but most especially the Kesselbrunnen of Ems, the Theresienbrunnen of Carlsbad, and the waters of Vichy.

Counter-irritants applied to the epigastrium in obstinate cases have seemed to afford relief, but more permanent benefit has appeared to us to follow the continued use of a warm emollient opiate or Burgundy plaster. The warm douche upon the stomach, as used at the baths of Lucca and at other thermal springs, we have known to be of considerable use in this way.

Relaxation and repose of mind prove frequently of themselves a cure for this complaint, by which the disturbed functions recover themselves; and to a certain degree they are essential to the success of the general plan of treatment. Though we may not have the power of throwing off the burden as we will, much is to be effected by disposing of the mind to it. By a gentle steady effort it may be subdued to a state, if not of ease, certainly of quietude. They who know how to appreciate health will not hesitate to make any sacrifice, and they who cannot or will not make the sacrifice, may still do much to correct their habits. If they cannot have entire relaxation, they may seek to change or interrupt their occupations: "*Levat quoque lassitudinem etiam laboris mutatio.*" And if they cannot conquer the habit which care and anxiety have established, they may obtain much by seducing the mind into other occupations.* "*It is upon this account,*" says Cheyne, "*that I would earnestly recommend to all those afflicted with nervous distempers, always to have some innocent entertaining amusement to employ themselves in for the rest of the day, after they have employed a sufficient time upon exercise, towards the evening, to prepare themselves for the night's rest. It seems to me absolutely impossible, without such help, to keep the mind easy and prevent its wearing out the body as the sword does the scabbard; it is no matter what it is, provided it be but a hobby-horse, and an amusement to stop the current of reflection and intense thinking, which persons of weak nerves are apt to run into. The common division of mankind into quick thinkers, slow thinkers, and no thinkers, is not without foundation in nature and philosophy. Intervals of no thinking or Swiss meditation are necessary for health.*" Under this impression it has often occurred to us that the innocent pastimes of life are very much

* Vita namque tamdiu in perturbatione est, remedia nequicquam proficiunt, et licet ea recipiat, viribus tamen illorum non auscultat.—*Bagliui.*

undervalued, and we have not hesitated to recommend our patients their quiet rubber of whist, a party at piquet, a game at draughts or backgammon, even chess, or any thing by which the mind is amused without being excited; light occupations of the mind which divert the attention without occupying or fatiguing it; light reading, arithmetical calculations, any game where the stake excites no interest: music (*flute-playing*), drawing, embroidery, and every description of handy-work. We have also known the greatest advantage derived from practising some of the mechanical arts; one of the most inveterate cases of irritable dyspepsia we have known was very much alleviated by the patient taking to the employment of turning.

But frequently all these objects are most completely attained by a tour, a sea voyage, a change of air, which, including change of food, of exercise, occupation, and habits, invigorates the body whilst it relaxes the mind.

The general irritability of the body is much diminished by an open dry air, and by dwelling in it as much as possible; by a long sea voyage in severe cases, by the use of the rocking-chair, the rocking-sofa, and by the swing. But the restoration of no function tends so effectually to calm the irritation and repress the jaded fibres of the body as sleep, and we are of opinion that this, which is left to return as an effect of the general improvement, might probably be advantageously solicited and sought for, as a means as well as a consequence of recovery, if possible, by the more natural means, by gentle exercise in the open air, by early hours, by tepid baths, proportioned in duration to the strength of the patient, the warm pediluvium; but if these are not successful, by anodynes, by the acetate or muriate of morphia, or the black drop, judiciously managed, so as not to derange the function of digestion. This object is so important that it is often desirable to give up an hour or two in the middle of the day to sleep. If the tepid bath does not produce headach or sleeplessness, it is always of service; but to the extreme cases of the disease, where the patient's strength is much exhausted, it is not applicable.

The temperature of the body is to be supported by warm clothing; a flannel roller is of great use; and medicines determining to the skin often afford relief, as ipecacuanha or James's powder in small doses, combined with extract of hyoscyamus. The tone of the body will be invigorated, and the morbid irritability directly diminished, by dwelling much in the open air in a dry temperate atmosphere. We are convinced that, besides the influence of change of habit, this is one of the most important effects of passing a winter in the south of Europe. This effect we have known many persons feel most sensibly, saying they felt as if their nerves were loosened and set free—as if they were out of fetters. When the patient's sensibility is not too delicate, the daily cold ablution is of great service; and in a higher degree of strength the shower-bath may be used with advantage.

3. Provided the bowels are properly regulated, and the function of the liver correctly

performed, some tonic medicines may be had recourse to; but if the preceding plan be faithfully executed, their use will be found of secondary importance. Whatever quiets and strengthens is expedient in irritable dyspepsia, and tonics and stimulants often appear to possess a specific effect in subduing irritable action of the nervous system. They consist of the sulphate of quina, which some have administered endermically; steel in its various preparations. Pemberton was in the habit of giving Griffith's green draught. The ferrum ammoniacum is a convenient form, or the vinum ferri. The carbonated chalybeate waters are frequently successful when no official preparation of iron can be borne, chiefly those of Eger, Spa, and Pyrmont. The irritability is also sometimes diminished by a judicious use of stimulants, but it is a practice which demands much judgment and discretion.

The secondary forms of this disease must be treated by a proper consideration of the primary disorder in which they originate; and for the cure of the secondary affections which originate in irritable dyspepsia, we must refer to the separate articles to which they belong. In conclusion we cannot better explain our notion of the principle which ought to preside over the treatment of this disease in all its forms than by quoting the words of Baglivi: "Blandè et leniter tractandi sunt; a nimia remedium copia et vehementia quam maxime abstinendum."

IV.—*Follicular gastric dyspepsia.*

Synonyms.—Stomachi pituita, *Cels.*; rheumatismus vel fluor stomachi, *Cæl. Aur.*; cardilæa, *Plateri*; anorexia pituitosa, vomitus pituitosus, cardialgia bradypeptæ, *Sauvag.*; anorexia humoralis, *Cullen*; catarrhe de l'estomac, *Pinel*; estomac glaireuse, *Fr.*; pain of the stomach, most felt when the stomach is empty, *Pemberton*.

General character.—Pain, nausea, cramp, sensation of gnawing, of weight, or other uneasiness in the stomach, chiefly felt in the morning or when the stomach is empty, and frequently followed by vomiting of an insipid, viscid, subpellucid fluid.†

Form of disease.—This species of dyspepsia is chiefly met with in capricious old people, and in young persons of a cold phlegmatic temperament about the age of puberty. It prevails most in cold and damp climates, and in cold and damp seasons; it is the usual attendant of the winter cough of old age, and frequently supervenes in the course or upon the decline of a catarrh, and is usually relieved in summer and aggravated in winter. It is commonly manifested by pain, a sense of weight, of gnawing, sometimes by craving, or by obtuse spasmodic pain, or other uneasiness, when the stomach is empty; by loss of appe-

* *Doussin*.—*Dubreuil*. Des Glaires, de leurs causes, et de leurs effets. Paris, 1831.

† Est ea quæ a viscosis adiposis, lentis humoribus in stomacho contentis excitatur; quod cognoscitur ex sensu gravitatis in ventriculo, ructibus insipidis, vomitione pituitæ insipidæ glutinosæ, ex assumptis oleosis, pinguibus sensu expletionis.—*Sauvages*.

tite, nausea, and sometimes by vomiting of a transparent ropy tasteless fluid, clear and glairy like the white of an egg, more generally in the morning, but sometimes towards night. The nausea and other uneasy sensations of the stomach are usually very much relieved by the rejection of this fluid, the quantity of which is in some cases very considerable. In a woman mentioned by Andral this discharge amounted to about four pints in the twenty-four hours; and, what is remarkable, she never vomited either food or drink, shewing this fluid to be highly offensive, and a source of irritation to the stomach.* The pain and uneasy feelings of the stomach sometimes assume the form of *pyrosis*, accompanied with a copious flow of saliva, or a continual watering of the mouth, corresponding with nausea, or a sensation of gnawing at the stomach.† Besides these more specific symptoms, this disease is attended by those which are common to the other forms of dyspepsia, by flatulence, by eructations of flatus or fluid, generally insipid, sometimes slightly acid; by oppression at the stomach after eating, although the pain and uneasiness are considerably diminished by taking food. There is a frequent desire to take food, attended with thirst, and as the disease continues, there is also considerable wasting of the flesh. The uneasiness produced by laborious digestion subsides as the process is finished, but before the time of taking food arrives, the stomach becomes irritated by its own secretion, which produces all the inconvenience of a foreign indigestible substance in that organ, such as a sense of sinking, of dragging or trembling of the stomach, of nausea, faintness, gnawing or erosion, which are again for a time relieved by the taking of food.‡

The distension of the stomach by flatus sometimes gives rise to great oppression or anxiety at the stomach, to the same sensation in the breast, and to vertigo and other uneasy feeling in the head, to palpitation or irregular action of the heart, trembling of the knees, and coldness of the feet and legs. These symptoms are generally relieved as the flatus is expelled, which is, however, accomplished with more difficulty in the recumbent posture; if not accomplished, restlessness, agitation, requiring a constant change of posture, frightful dreams, or incubus, are common attendants.

In this form of dyspepsia there is generally some thirst; the tongue is covered with a viscid mucus; sometimes the papillæ only are tipped with a dull white fur, but frequently it presents a continuous white fur and a sodden appearance; under irritation the tongue becomes dry, presenting a shining or glossy appearance, but still continues paler than natural. The bowels are generally confined, and the evacuations scanty; sometimes large quantities of mucus, generally fluid, sometimes concrete, are mixed with them. The urine is

usually high-coloured, seldom sedimentous. Unless there be great debility, the pulse is slow and soft, and the extremities are generally cold.

The sympathetic affections which characterize this form of dyspepsia are, a troublesome cough, with considerable mucous expectoration, which is much increased by taking food, dyspnoea, humoral asthma, and leucorrhœa. It has also appeared to us that *acne*, in some of its forms, is a disease of the skin very frequently connected with this particular derangement of the digestion; and we have had occasion to notice a form of rheumatism, accompanied by palsy of the parts affected, which frequently attends it,—that species which has from some physicians received the name of *paraplexia rheumatica*. Sympathetic headach is less common.

Causes.—The predisposing causes of this disease are a phlegmatic temperament, natural or acquired; the decline of life, that period after the forty-fifth year, the *senium crudum*, green old age, *l'âge de retour* of the French; the latter part of childhood, the period bordering upon puberty, before and after; damp climates, damp seasons, and damp weather; low marshy situations; indolence of body and mind, and sedentary habits. The ancients thought that particular kinds of food, also, favoured this predisposition: “Crassiores autem pituitam faciunt ova sorbilia, alica, oryza, anylum, ptysana, lac, bulbi, omniaque ferè glutinosa.”* Some physicians have also considered it to be more common in great ale-drinkers and smokers.

The exciting causes are accidental indigestions from food of an improper quality, and catarrhal colds.

This disease may succeed to atonic as well as inflammatory dyspepsia, probably presenting in each case a corresponding variety, a circumstance which leads us to doubt whether we are perfectly correct in erecting this form of dyspepsia into a distinct species, and whether it might not have been more so, to have arranged each of their varieties as sub-species respectively of atonic and inflammatory dyspepsia. But not having been able to distinguish these varieties by their proper symptoms, we must leave the task to a better method and a more refining analysis.

Pathology.—This species of dyspepsia was noticed by Hippocrates as a form of repletion, was clearly distinguished by Celsus,† and described by the sect of Methodists as a variety of their *stomachica passio solutionis* under the term *rheumatismus stomachi*, using that term in its etymological sense of fluxion, and not under its modern arbitrary limitation. Under *anorexia pituitosa* and *vomitus pituitosus*, corresponding with the French term *estomac glaireux*, Sauvages has correctly laid down this species of dyspepsia, and Cullen has included it in his local disease of *anorexia humoralis*. We may also find that this form

† Interdum stomacho pituita oritur.

of disease (or its appropriate symptoms) has not escaped the observation of most of our best writers; but it was more particularly singled out by Dr. Thomson in the Edinburgh Medical Essays, by the late Dr. Pemberton in his practical work on the diseases of the abdominal viscera; and we are of opinion that the disease to which Daubenton had his attention chiefly directed, was this particular form of dyspepsia.* We form our opinion on this point, however, as much from the nature of his remedy as the description of the disease, for he has indeed only described the symptoms common to slow and laborious digestion, the *concoctio tarda* or *brudypepta* of some authors.

The older physicians attributed this disease to a cacochymy of the fluids by which the cold phlegm becomes predominant, and they thought to explain the disorder by describing it as a fluxion of the degenerated humour to the chylopoietic organs. But there can be little reason to doubt that, however it may be induced, the proximate cause of this disease chiefly consists in a disordered state of the mucous follicles of the stomach, the *glandulae aggregatae et solitariae* of anatomists. The nature of the symptoms will not acknowledge any other cause, and it would be difficult to find any other morbid condition to account for the peculiar matter so frequently vomited. That the disorder of the function of the mucous follicles may be frequently only a part of a more general derangement of the mucous surfaces of the stomach, is highly probable; but that the disorder also frequently predominates in the mucous follicles—nay, is sometimes exclusively confined to them,—we have ample proof in dissection, and it would certainly be highly unphilosophical not to admit it as a morbid condition of the stomach capable of giving rise to its own peculiar form of indigestion.

The disease of the follicles may be simply functional, or it may be organic, and both of these morbid conditions admit of great variety. Dissection shews us that a disordered state of the secretion of the mucous follicles may proceed from very different states of these organs. It may be the consequence of an increased development of the follicles which sometimes succeeds to inflammation, but frequently arises without it. In persons who had formerly suffered from gastric irritation, an increased activity of the secretion, and a remarkable development of the follicles, have been observed. "In opening certain bodies," says Andral, "we are struck with the vast quantity of mucus which sometimes covers the inner surface of the stomach or intestines. This mucus often forms a thick coating extended over a considerable surface. At the first view we might mistake this coating for the mucous membrane itself, which presents a white healthy appearance. Under the covering of mucus, the surface of the mucous membrane may, however, present itself in two very opposite states. Either there

may be found under the mucus a bright redness of the membrane by which it has been produced, the more common state; or it may be found pale and without any trace of redness or injection. For the augmentation of a secretion does not necessarily imply the notion of a sanguineous congestion of the secretory organ."† It is possible, as we have already remarked, that these two opposite pathological states may also afford a distinction of symptoms to be hereafter ascertained by a clearer and finer observation, which may divide this form of dyspepsia into two different varieties, each arranged under their respective species of atonic and inflammatory dyspepsia.

That the accumulated mucus is the proximate cause of much of the painful feelings in this form of dyspepsia may be inferred from the relief which is experienced on its being ejected, as well as from its sometimes being the only thing which is ejected, the food and medicine being constantly retained. "The increased secretion of the glands of the mucous membrane of the stomach," observes Pemberton, "irritates the nerves of the stomach and thus causes pain. When it is secreted in small quantities, it may be so enveloped by any food that is taken as to render it inert; or when it is secreted in larger quantities, it may be thrown up by vomiting after causing violent pain." For being indigestible by the stomach, when it accumulates, as it most frequently does during the night, it becomes a kind of foreign substance, the source of much irritation, giving rise to a great variety of uneasy and painful sensations, and frequently to habitual daily vomiting, a complaint which M. René Prus considers the cause of a considerable number of cases of hypertrophy of the muscular coat of the stomach, frequently mistaken for cancerous degeneration of that organ.

Method of cure.—As in every species of dyspepsia, so in this, the method of treatment must necessarily consist of the following indications:—1. to render the process of digestion as easy as possible by a selection of food proper in kind and quantity, and suited to correct the morbid condition of the stomach: 2. to excite the function of digestion by exercise adapted to the strength and habits of the patient, calling forth the stimulus of demand: 3. to promote the function of digestion by restoring the harmonious action of the different parts of the alimentary canal, chiefly by preserving an open state of the bowels; and 4, to correct the particular morbid condition, the specific and proximate cause of this form of dyspepsia.

1. The patient should in his diet observe a cautious economy of liquids; his meals should consist chiefly of solid food, of the lean of animal food of such kinds as are easy of digestion, avoiding all that is fat, glutinous, and tough. His meat should be thoroughly dressed, never twice cooked, and his food should be taken hot. In general he should avoid fish, fruit, vegetables, cheese, milk, and eggs. Vegetables are at all times to be eaten sparingly; if prepared in the French fashion, they are certainly less un-

* Daubenton on *Ipecacuanha*. Lond. 1806.

† Patholog. Anat.

wholesome; but cabbages, all roots, and all bulbous vegetables, and all of a flatulent nature, are to be strictly forbidden. He should be careful not to drink before his meals; but plain light soup or broth, impregnated with the juice of vegetables, may be permitted in small quantities. Bread should be eaten stale, and the quantity should be limited. Malt liquors of every description are prejudicial, but a glass or two of dry wine, of sherry, sauterne, hock, or white hermitage, or a proportionate quantity of brandy and water may be allowed, and is frequently very useful. For breakfast, coffee is to be preferred to tea; and it is also in this case a good stomachic after dinner. Butter may also be permitted in moderate quantity; but whatever be the diet selected, the rule which is universal in dyspepsia, must not be forgotten—that a small meal of whatever kind is, *cæteris paribus*, more easy of digestion than a bulky one; and that by whatever plan of diet the patient has been restored, he must adhere to it for a considerable time after his recovery.

2. Horse exercise is the most suitable in this species of dyspepsia; but active walking, even to a certain degree of fatigue, sufficient to produce moderate perspiration, is frequently of great service. The exercise of the arms by the dumb bells or fencing, of the chest by singing, reading aloud, or declaiming, is of much importance, and ought to be sedulously persevered in. Great advantage has also been derived from boat-sailing and sea-voyages, whether from exciting vomiting we cannot say; but no description of exercise ought to supersede friction morning and evening, either with the flesh-brush or with a glove made of a piece of coarse blanket; and, for obvious reasons, it is more useful when performed by the patient himself than when administered by an assistant.

3. The best aperients in this disease are the decoct. aloes comp. which is sometimes advantageously combined with lime-water; or pills consisting of equal parts of aloes, rhubarb, calumba, and soap; or equal parts of the pil. rhei comp. and pil. galban. comp. or pil. scill. comp. We have also found the lac sulphuris an aperient well suited to this complaint. The object ought to be to obtain easy, satisfactory, and consistent evacuations, which the lavement alone is seldom able to accomplish; but it may be used to promote the operation of other means.

4. In the early stage of the disease the disordered state of the mucous follicles is sometimes quickly and readily corrected by an emetic, probably by exciting and evacuating their contents. For this purpose ipecacuanha is to be preferred; and, when requisite, it may be rendered more active and efficient by combining it with the acetum scillæ. But though emetics, by stimulating and emulging the follicles, do afford considerable relief, their frequent repetition is not advisable; and in the more advanced state of the disorder, where vomiting becomes sometimes one of the most troublesome accidents of the disease, they cease to be serviceable. It has been found that, if ipecacuanha, instead of being taken in doses

sufficient to excite vomiting, be administered in repeated small doses, it is of much more permanent use. With this view Dr. Thomson* was accustomed to divide a full dose of ipecacuanha into several equal parts, which he directed to be taken in the course of twenty-four hours; and in the same way he was accustomed to divide a full dose of an aperient, (his favourite was the old-fashioned tinct. hieræ picræ, well replaced by our tr. aloes comp.) which he gave in the same way, in separate portions, alternating a course of aperients with a course of emetics. Daubenton used ipecacuanha apparently upon the same principle in much smaller quantities, restricting his dose from a quarter of a grain to two grains, just sufficient to occasion a slight vermicular motion in the stomach, but he only gave it once in the twenty-four hours, in the morning fasting.† Herecommends it to be given in water, wine, jelly, or in a lozenge. It is sometimes conveniently combined with the aperient. Where nausea is easily excited by it, we have been in the habit of uniting it with a little sub-carbonate of ammonia, aromatic powder, cayenne pepper, or sulphate of quina; when flatulence is troublesome, with the pil. galb. comp. or the pil. scill. comp.; and when symptoms of acidity are present, we administer it in lime-water: we have often seen much advantage from modifying its action by such auxiliaries.

The sulphuret of potass in doses from a few grains to half a drachm alone, if the sensibility of the stomach does not forbid it, or combined with subcarbonate of ammonia, bitter extracts, aromatics, carminatives, with rhubarb, aloes, the pil. galb. or pil. scill. comp., as circumstances may indicate, is another remedy appearing to possess a specific action upon the mucous follicles. It is probably from a similar property that the sulphureous waters, as those of Harrowgate, Balaruc, Cauterets, and several others, have been found such efficient remedies in this disease.

Heidler of Marienbad also relates several speedy and perfect cures of this complaint by means of the Kreuzbrunnen mineral water. We have reason also to speak highly of tar water and lime water as valuable correctives of this morbid state of the mucous follicles.

Pemberton placed his chief reliance upon opium in union with astringents. In the incipient stages he was accustomed to give ten grains of kino and half a grain of purified opium, made into two pills, every fourth hour. He preferred kino to any other astringent, because, unless there was diarrhœa, it appeared to have no tendency to confine the bowels. This is not very different from the method of Prus, according to which Andral treated, at La Charité, a man who had for a long time vomited a certain quantity of transparent mucus resembling a strong solution of gum arabic in water. He gave him for a month from one to six grains of the watery extract of opium daily. The vomiting disappeared, and under the influence of this medicine, the ordinary effect of

* Op. cit.

† Op. cit.

which is to disorder the digestion, the function of the stomach was entirely restored.

The good effect of these remedies may be protracted or increased by a suitable use of tonics, either bitters or chalybeates. The vinum absinthii was once a favourite remedy in this complaint. The pil. ferri comp., vinum ferri, tr. murialis ferri, and ferrum ammoniatum are suitable forms of chalybeates, care being taken that the bowels are at the same time preserved in a soluble state. But the chalybeate mineral waters of Eger, Spa, and Pyrmont are much to be preferred to any medicine of the same class.

The morbid condition of the mucous follicles may also be corrected by exciting the action of the skin, by increasing its tone and vigour by friction as already noticed; but also by cold ablation with vinegar and water, or salt and water; by the nitro-muriatic lotion, by cold affusion, or the shower-bath, remedies corresponding to the *ψυχρολουσία* of the ancient Methodists. And in addition to them, if circumstances permit the patient to choose his place of abode, he should seek above all things for a dry air, that of the mountains in summer, and of the sea-side in winter; and to fulfil the last intention, the best climates of which we have experience are Nice, Genoa, and Brighton. But wherever the patient may live, he should as much as possible select the driest situation, where the drainage, natural or artificial, is most perfect.

II. DUODENAL DYSPEPSIA.

Disordered digestion proceeding chiefly from derangement of the functions of the duodenum, and the other small intestines.

To say precisely where duodenal dyspepsia begins, or where gastric dyspepsia ends, would not be an easy matter. Subordinate processes in the performance of a complex function, conspiring for one general effect, the healthy actions of the stomach and duodenum, though different, are not easily to be distinguished; and though in disease their difference becomes more developed and more apparent by their discordance, it is more easy to describe than to mark the line which divides them. Nature indeed never separates things by strong or abrupt lines, though she stamps each with features sufficiently bold and clear to distinguish it from its neighbour. Her system is one continuous tissue of great variety and diversity, in which different parts are united together without sign of interruption or joining. In the coloured spectrum no one can say where one colour ends and where its neighbour begins, yet any one may distinguish its different colours, the violet from the blue, the blue from the green, each from its neighbour, and every one from the other. So in diseases having an affinity, where they approach each other they cannot easily be distinguished, whilst in their general character it would be difficult to mistake them. And, likewise, in the function of digestion, though such is the functional dependence of one part of the alimentary canal upon another, that one being affected speedily induces disorder in the remainder, yet attentive observation will dis-

cover the part primarily and chiefly deranged, the leading features, the permanency of some symptoms, indicating directly the part affected; whilst the more variable and less marked character of other symptoms excludes the derangement of other organs.

General character.—Appetite generally little impaired, frequently keen, sometimes ravenous; the oppression, distention, pain, or other uneasy sensations, the signs of difficult digestion, not referred to the stomach, nor felt soon after taking food, but a considerable time, generally from two to four hours, after a meal; urine sedimentous; fæces more or less unnatural in appearance.

Although Hippocrates had distinguished between gastric and enteric dyspepsia, it would be difficult to single out from amongst the diseases described by the ancient physicians, any precisely corresponding with those of which which we are about to treat, though most of their symptoms might be found in the *ventriculosa passio* and *phagedæna* of Cælius Aurelianus, and in the *morbus atrabiliaris* and *morbus hepaticus* of the Greeks. Amongst modern writers it may be detected under the terms of *intemperies hepatis*,* *infarctus hepatis*,† *dolor hypochondrii*,‡ *hepatalgia*.§ But it was not until a knowledge of the anatomy and functions of the human body directed the researches of the physician, that the symptoms of these disorders began to be classed together, and the diseases to be traced to their seat. Hoffmann,|| who dignified the duodenum with the name of the second stomach, and, because of the secretions poured into it, *ventriculus succentriatus*, commenced this important task, in which he was afterwards followed by Bonnazoli,¶ an academian of Bologna, by the elder Monro,** at a later period by Dr. Claisen,†† and more recently by Dr. Warren;‡‡ but the subject remained incomplete until the very scientific and practical essay of Dr. G. D. Yeats§§ on the diseases of the duodenum, delivered as the Gulstonian lecture for 1817. Availing ourselves of the assistance of our predecessors, we accordingly propose following the same course in treating of *duodenal dyspepsia* as we have attempted with *gastric*, dividing it into species according to the morbid condition of the organ, the essence and proximate cause of the disease. We should therefore have to speak separately of *atonic*, *inflammatory*, *irritable*, and *follicular*, *duodenal dyspepsia*; but the irritable form of the disease we do not profess to have yet ascertained. To the second of these species we propose subjoining a variety

commonly met with in scrofulous habits, which may with propriety be distinguished by the name of *strumous dyspepsia*.

I.—*Atonic duodenal dyspepsia*.

Synonyms.—Hepatalgia infarctus, intemperie frigida; aurigo frigida ab obstructione; gastrodynia biliosa, *Sawages*; chylipoietic disorder, *Abernethy*; bilious dyspepsia, *W. Philip*.

General character.—Sense of weight, fullness, or distension, or a heavy, dull, dragging, pain in the right hypochondrium, felt generally some hours after eating; bowels confined; evacuations unnatural; urine dark-coloured and sedimentous; pulse slower than natural; skin rather sallow, and conjunctiva generally tinged with bile; no fever, but considerable languor and oppression.

Form of disease.—When a person labouring under this disease comes to consult a physician for his complaints, it will seldom be found that he blames the state of the digestive organs, but, on the contrary, his physician will sometimes find him quite unconscious of their being in a disordered state; for his patient will tell him that his appetite never fails him, that he never finds any kind of food disagree with him, and therefore he is quite clear that his digestion has nothing to do with his ailments. He may complain of headach, affecting more particularly the back part of the head; of pain of the back, or under the right scapula; of lumbago, or pains in the joints; of pain or numbness of the right arm; of cough, dyspnoea, languor, loss of strength, or depression of spirits, or of many other similar sympathetic affections, but the disorder of the digestive organs has never drawn his attention. If, however, the physician enters into particulars, he will find that though the appetite be good, the digestion is laborious; that not immediately, but a considerable time after eating, the patient is oppressed, drowsy, and incapable of either mental or bodily exertion, and that he awakes from a nap uneasy, restless, fidgetty, and irritable. This state of general discomfort is frequently attended with a sense of fullness, distention, or weight towards the right side, or with a heavy dull pain felt chiefly in some part of the right hypochondrium. This pain in the right hypochondrium extends sometimes to the back, frequently between the spine and the right scapula, or under the right scapula, or it corresponds with a dull pain felt chiefly at the top of the shoulder, or with numbness or dull pain extending down the right arm to the elbow, wrist, and little finger, more rarely with pain of the right hip, extending down the right leg. Under certain circumstances these symptoms are very much exasperated, and the pain in the right hypochondrium becomes very acute, accompanied with great anxiety or with spasm in the situation of the duodenum, and a sensation of weight in the hypochondrium and loins, amounting to a complete attack of gastrodynia. If the right hypochondrium be examined, more especially if the examination be made when the patient is in the erect posture, a fullness will be perceptible through the whole hypochondrium, more sensi-

bly apparent when compared with the left; sometimes a circumscribed puffiness is perceptible in the site of the duodenum, most particularly just before the cartilage of the eighth rib, in which situation it is observed that pressure is disagreeable, sometimes occasioning a sense of oppression or dyspnoea. This puffiness not unfrequently disappears in a day or two, particularly after free evacuations of the bowels, and then gradually returns, but is sometimes quite stationary, and occasionally so obvious as to be observed through the clothes, more especially in females. On some occasions it is so circumscribed and prominent as to give almost the appearance of a hernia. Such a case we have met in consultation with our amiable and lamented friend, the late Professor Andrea Vaccà, of Pisa, which appeared to derive considerable relief from the pressure of a bandage. Instead of pain or sense of weight in the right hypochondrium, there is occasionally a feeling which conveys the notion of torpor, of stoppage in or dryness of the bowels, as if their contents made no progress downwards, to which frequently corresponds a sensation of fullness in the lower bowels, leading to ineffectual efforts to relieve them, and not rarely spasmodic stricture of the rectum. Or there is soreness or a sense of fullness below the pit of the stomach in the situation of the arch of the colon, but deeper-seated. These affections are disposed to occur in paroxysms, seeming to be connected with the state of digestion, for the symptoms are more or less relieved as the process of digestion is completed, or they are relieved by satisfactory evacuations of the bowels, and relief is even experienced as soon as the upper portion of the bowels is put in motion, often long before an evacuation.

With the above symptoms, distinctly referable to the seat of the disease, or in place of them, the patient may complain of headach, which, generally unaccompanied with nausea, commences with a feeling of uneasiness of the head, with indistinctness of ideas, and disinclination or incapacity for mental exertions, chilliness of the body, coldness and dampness of the hands and feet. The headach itself consists in a pain or dull aching, sometimes of the forehead, but more commonly of the crown or posterior part of the head, which is attended with restlessness, with intolerance of noise, with dazzling or mistiness before the eyes, or with the appearance of various colours or luminous forms. The headach is invariably much aggravated during the period of digestion; sometimes it terminates with the process of digestion in a few hours, but when it has become habitual, it may continue for one or two days. Instead of headach there is sometimes a sense of fullness or of distention of the head without any fixed pain. Vertigo is occasionally the most troublesome symptom, and we have known it to persist uninterruptedly for weeks together; or the patient being seized with temporary loss of consciousness, and of muscular power of the limbs, falls down suddenly without syncope or convulsion. Contractions of the countenance,

rolling of the eyes, cramps or numbness of the limbs, are very common symptoms, and even hysteria, chorea, a fit of epilepsy or apoplexy, are not rarely connected with it. Rheumatic gout, aching pain in the knees and ankles, particularly of the right side, lumbago, pain of the back, especially in the direction of the right kidney, commonly aggravated by the recumbent posture, languor, lassitude, and weakness of the limbs, feeling as if the legs would give way, and sometimes actual paraplegia, are amongst the secondary affections of this disease. Fluttering, irregular action, and sense of distention of the heart, irritation of the larynx or trachea, causing a constant hawking or effort to expectorate, singultus, dyspnea, and even asthma, are not unusual symptoms. A degree of spasm, sometimes stricture with a sense of weight or load about the rectum, spasmodic stricture of the urethra, or difficult micturition, are not rarely observed in this complaint. The various forms of *epheles*, *pityriasis versicolor*, some species of *herpes*, particularly *herpes præputialis* and *circinnatus*, the *impetigo sparsa*, are the diseases of the skin which we have most frequently remarked as connected with this complaint, and their eruption is not rarely attended with relief of the internal disorder. Indolence, sluggishness, listlessness, or indifference of temper, want of the usual distinctness of ideas, a feeling of a cloud over the intellect, loss of memory, confusion of intellect, or oppression of spirits, are characteristic symptoms of this disease.

With more or less of the foregoing symptoms, either directly referable to a deranged state of the digestion, or secondary consequences of it, the appetite is observed to be seldom impaired, but on the contrary soon returns after eating, and even during the period of suffering is often preternaturally increased and voracious, sometimes unusually keen, particularly for food which disagrees, which last proves not seldom a premonitory symptom of an exacerbation of the complaint. The tongue is large, broad, soft, and flaccid, covered with a yellowish white mucous fur towards the root, but moist, slimy, and of a dull red colour towards the point and margin, presenting in general a flabby and sodden appearance. The bowels are costive, more rarely alternating with occasional diarrhoea, and the alvine evacuations when costive are hard, dry, and adust, of a dark brown or dull olive or greenish black colour; if more lax, generally of too light a colour, resembling that of whitish brown paper, of a dull clay or light brownish colour, and devoid of their natural smell; or sometimes yeasty, tape-like, sometimes of a faint yellow colour floating upon the water, giving out an odour like that of saliva, or frequently containing bits of undigested food, uncombined bile, or occasionally consisting chiefly of bile. The urine is unhealthy, not remarkably deficient in quantity, but dark-coloured, of a deep colour like that of mahogany or stale beer, but always sedimentous, either lateritious, or yellow, or cream-coloured, but more generally white and furfuraceous, and so copious as to be thick

throughout like gruel, its surface being generally covered with an oily iridescent film. The pulse is soft, slower than natural, sometimes preternaturally slow or labouring, frequently intermitting or irregular, faint, and fluttering. The skin is dry, dull, flaccid and inelastic, and sallow, and the eye dull and tinged with bile. The feet are habitually cold, the sleep is heavy and unrefreshing; the patient either awakes frequently in the night, or is troubled with disagreeable dreams, and, instead of being refreshed, is oppressed with fatigue in the morning. When the preceding signs of deranged function of the organic system present themselves in combination with some of the complaints or sympathetic affections above specified, there can remain little doubt that they are referable to a deranged state of the duodenum, of which distention or irritation of that intestine is the consequence; and if the preceding signs of derangement of the organic system be present without any complaint, the physician may be sure that a process of disease is in progress which will sooner or later declare itself.

Pathology and causes.—The particular process of the function of digestion, which is more especially deranged by this disorder of the duodenum, is that which, consisting chiefly in the mutual actions and re-actions of the chyme, the bile, and the other intestinal juices, has hence received the name of *encholosis*, and of which the result in health is chilification; and the proximate cause of this derangement is no doubt a pathological condition of the duodenum, consisting partly in deficiency of tone, partly in deficiency of sensibility, from which arises discordant action in relation to the stomach on the one hand, and the intestines on the other. For the duodenum allowing of the accumulation of the chyme, an impediment is opposed to the function of the stomach; the secretion of the bile, depending on the healthy state of the duodenum, is imperfectly solicited, and the peristaltic motion of the intestine being impeded, its discharge into the intestine is obstructed; while the other intestines cease to receive, both in kind and quantity, their natural material of operation. This disordered state of the duodenum rarely, however, originates in itself; from its intermediate position, it is more generally a consequence of an imperfect performance of the function of the stomach or of the large intestines; sometimes, but more rarely, it originates in the liver. If the stomach have not sufficiently subdued the food to a healthy and natural chyme, the duodenum becomes the recipient of unnatural ingesta, unsuited to its particular function, from which disorder must ensue. This state of things appears to us to be more liable to occur to those who, fasting long, are apt to swallow their meals hurriedly, and therefore masticate their food imperfectly, or to those who, ever intent on the business of life, eat, as they think, quickly,—a habit very constantly induced in those who have contracted the pernicious practice of reading or transacting business at their meals. The same effect which arises from the hurried, imperfect mastication

of wholesome victuals, may also be induced by the ingestion of indigestible substances, and therefore the use of such things as the stomach has no power of digesting frequently leads to duodenal dyspepsia, as for instance, nuts or the kernels of fruits, hard indigestible fruits, crude vegetables, the seeds and skins of fruits and vegetables, cherry-stones and similar substances. The same consequence follows for the same reason in some great feeders, whose pylorus allows imperfectly digested food to pass; in this respect some persons, and particularly children, seem to have a great facility.

But a disproportionate quantity of the healthiest chyme poured into the duodenum quicker than the process of *encholosis* can be performed, or than its transmission can take place, must lead to precisely the same result as the passage of chyme imperfectly elaborated. This is the reason that children are proportionately more subject to duodenal dyspepsia than adults; for having in general a good appetite and a powerful gastric digestion, they are wont to eat at all hours and seasons, taking a second meal before the first is digested, so that the duodenum becoming distended with chyme which it cannot transmit, interrupts the discharge of the bile, and accumulation takes place. Of this we have a proof in the crapulous diarrhœa consisting of light-coloured stools which so often ensues. "Children," says Dr. W. Philip, "are still more inclined to this accumulation than adults, most of their complaints being connected with this state of the digestive organs. Of children who are out of health, with the exception of those labouring under contagious diseases, not one in twenty will be found free from more or less of it; and their restoration to health is never permanent till the due action of the first intestine is restored." Precisely the same effect will, in the same manner, be produced by any cause impeding the transmission of the chyme from the duodenum onwards, though it be neither unnatural in quality nor disproportionate in quantity; thus leading to accumulation in the duodenum, to distention, and all the consequences of duodenal dyspepsia. Now this may arise simply from a confined state of the bowels, which, gradually propagated upwards, ends in inducing duodenal dyspepsia; thence we find that healthy people having vigorous powers of stomach, who, from sedentary habits or confining themselves to the passive exercise of a carriage, have their bowels confined, readily become subject to this form of dyspepsia.

The accumulation of fæces in the colon, which in some constitutions, by sympathy, induces atonic gastric dyspepsia, also by its pressure upon the duodenum mechanically interrupts its free action, and prevents it from discharging its contents. And the same consequence results from the postures necessary in certain trades and professions, which have the effect of opposing the proper evacuation of the duodenum. This unhealthy posture is found in the highest degree in shoemakers as they stoop to their last; and we have certainly met with more cases of this disease in persons of

that trade than in any other. Tailors, engravers, and many others whose occupation requires the same posture, suffer in the same manner; literary people and clerks, from bending to the desk or table, frequently suffer from the same affection of the stomach; the stooping of women in their sedentary occupations of needle-work, and still more the pressure of the stays or tight lacing, tend in no slight degree to the same result.

An accumulation of chyme in the duodenum, in whatever way induced, soon lays the foundation of its own increase and continuance, for its immediate effect is to impede or interrupt the proper supply of the bile, either mechanically, (the pressure of the contents of the bowel closing by compression the oblique valvular orifice of the common gall-duct,) or by preventing the proper peristaltic motion of the duodenum which promotes the flow of bile, or lastly by deranging the sympathy of the duodenum and liver, so that the mutual actions and reactions of the bile and chyme—the process of *encholosis*—cannot have place, and the intestine is thus deprived of the natural stimulus for promoting the propulsion of its contents. In this way, therefore, a deficient supply of bile, without either an unhealthy state or an accumulation of chyme, may prove a primary cause of duodenal dyspepsia. Hence this form of dyspepsia is that which is induced by idiopathic icterus, and is reciprocally one of the most ordinary proximate causes of icterus. Or it may be that the sensibility of the duodenum being diminished or otherwise disordered, and the natural sympathetic relation between the liver and duodenum becoming deranged, the bile is not supplied in proper season, or a bile of a less active quality is secreted; for which reason the action of the duodenum begins to languish, and the disposition to accumulate is increased. Thus dyspeptics have for months, even years, a constant accumulation in this intestine; the duodenum never emptying itself thoroughly, a great portion of aliment is retained there beyond the due time, and is not evacuated before a fresh supply from the stomach has laid the foundation of other accumulations, until at last an enlargement evident to the eye as well as the touch often takes place.

This account of the manner in which atonic duodenal dyspepsia is induced, is in perfect accordance with the phenomena, explaining both the origin of the symptoms and the operation of the causes which more especially give rise to it. For we may thus see how the uncomfortable feelings in this form of dyspepsia are chiefly experienced a considerable time after taking food; how the stools present their unnatural appearances, how they are deficient of bile, resembling whitish brown paper, and sometimes as white as pipe-clay—an effect frequently observed to result from the action of opium upon the liver; how the chyme, being prevented from undergoing its proper changes, and accumulating, ferments and gives rise to diarrhœa of light-coloured sour-smelling stools; or how the bile, occasionally suppressed, occasionally accumulated, from time to time is copiously evacuated, and

a bilious diarrhœa is the consequence; how, the secretion of bile being suppressed or impeded, the kidneys assume a vicarious function, and discharging what ought to pass by the liver, give rise to the unhealthy appearance of the urine; how the duodenum, from derangement of its function becoming distended by gas or by the accumulation of chyme, or irritated by food imperfectly digested, or by substances indigestible, may by its extensive nervous connections be the source of all the various sympathetic affections above enumerated; and, finally, how inflammation of its mucous membrane or lesion of its structure may be the result.

The peculiar characters of disorders of the duodenum are well illustrated by a case of organic disease of that intestine related by Dr. Irvine, in the Medical Journal of Philadelphia for August 1824; several others are also upon record.

Treatment.—The morbid condition which constitutes the proximate cause of this disease readily suggests the indications for accomplishing the cure. These are obviously:—1. to afford present relief by unloading the duodenum; 2. to render the function of the duodenum easy of performance, *a.* by a proper regulation of diet, *b.* by proper exercise, *c.* by promoting a healthy secretion of bile, and *d.* by preserving an open state of the bowels; and 3. by seeking to correct the morbid condition of the intestine upon which the disease depends.

1. Unless the accumulation in the duodenum be the consequence of pressure from a loaded state of the colon, it is best evacuated by some aperient; otherwise an active enema affords the most immediate relief. For emptying the duodenum senna is the medicine which deserves the preference, being well fitted to promote the action of that intestine. Dr. Wilson Philip observes that it has appeared more effectually to remove the fulness of the right hypochondrium, when it depends on morbid distention of the duodenum, than any other medicine equally mild in its operation. It is best given in the form of infusion with an equal part of some carminative water or some light bitter infusion, and its action will be rendered more certain and more satisfactory by the addition of a small quantity of tartarised potass or tincture of rhubarb, which has also a tendency to prevent griping; but if this unpleasant effect be much felt, it may be avoided by the addition of a few drops of liquor potassæ, of spiritus ammoniæ aromat. or a small quantity of tr. cardamom. comp. to each dose of the medicine. When there is any disposition to fever, the infus. sennæ comp. of the Edinburgh Pharm. ought to be preferred. It may be combined with manna and tartarized potass. Where senna does not agree, rhubarb is the next best substitute. It may be given in substance in some carminative water combined with sulphate of potass or tartarized soda. For this purpose it is not necessary that the aperient should, according to the prevailing practice, be preceded by a mercurial purgative. Mercurials are more efficient and more necessary after the duodenum has been already

evacuated. The extract of colocynth, combined with extract of hyoscyamus, affords also a purgative adapted to this form of disease:—

R Ext. colocynth. comp.

Ext. hyoscyam. aa. ʒi.

T. fiat pilulæ xii. una vel bina hor. som. sum.

There can be no doubt that the duodenum is also sometimes spontaneously evacuated upwards by vomiting, and under certain circumstances this method may be imitated by art; but in general emetics are found to be of little use, and, failing in the object, are liable to do harm.

2. *a.* In order to lighten the burden of the duodenum, and render its function easy of performance, a careful selection of such articles of food as are generally held to be easy of digestion, and a scrupulous adjustment of the quantity to the powers of digestion, are of all things the most essential. The reader may refer for ample regulations on this head to the regimen of atonic gastric dyspepsia. We shall content ourselves with observing in this place that the patient should eat his meals slowly, and that he should masticate his food with the greatest care. In order to avoid infringing these rules he should endeavour to avoid long fasting, which leads to full meals quickly devoured. It is in this sense only that we can understand the reason of that old man's practice recorded by Lord Bacon in his Essays, who, when asked by what means he had preserved himself to so great an age, answered that he knew no other except that he never waited to eat until he was hungry or to drink until he was thirsty, by which he was able always to make a temperate repast; a rule of great value, provided we do not fall into the opposite extreme of eating too frequently. Small meals, then, eaten slowly and at moderate intervals, is the most comprehensive rule of regimen in this complaint. Patients should endeavour as much as possible to keep their minds disengaged at their meals; for they who are accustomed to read, or have their minds much occupied at table, are apt to eat fast and voraciously, and chew their food imperfectly. The food should be of that description which is entirely digested, and which leaves little excrementitious refuse. It should, therefore, consist chiefly of animal food, of stale bread, or moderate quantities of well boiled rice. Light refreshing broths, which are entirely digested in the stomach, afford occasionally a good form of nourishment in this disease; but they should be taken in moderate quantities, and not every day. Wine in small quantities is useful, but malt liquors are to be renounced.

b. The activity of the function of digestion will be excited by proper exercise of the body carried to a certain degree of fatigue: active walking over uneven ground, coursing, leaping, cricket, fencing, the broad-sword, or dancing, each proportioned to the strength and habits of the patient, are the exercises most to be recommended; reading aloud, declaiming, and singing are also useful. Horse-exercise is also well adapted to this form of dyspepsia, particularly when the patient's strength is at all impaired.

c. In endeavouring to restore the healthy secretion of the bile, some form of mercurial cannot easily be dispensed with; but the employment of this mineral should be so managed as to produce the desired effect upon the liver with as little injury as possible to the other parts of the system. All that is here wanted is something that may speedily correct the disordered function of the liver; and it is therefore unnecessary to give it so as to be received into the circulating system. To effect this object its local effect on the alimentary canal is all that is necessary; for, whether it act upon the liver by sympathy during its passage through the alimentary canal, or whether, absorbed from the alimentary canal by the radical branches of the vena portarum, and circulating through the liver, it stimulate that organ, its effect is so direct that it may be considered strictly local. It is best given in moderate doses repeated daily until the quality of the alvine evacuation or the state of the urine is decidedly improved. A few doses generally suffice; and its long-continued use is never necessary. It is more advisable to administer it in sufficiently active than in repeated small doses. The particular action sought for from the mercury is more certainly obtained by combining it with a small quantity of extract coloc. comp. or extract of aloes, to which a minute portion of the powder of ipecacuanha may be added. The pil. hydrargyr. is decidedly the best form of mercurial in this disorder. It may be given in doses of from two to four grains.

d. The impediment which is opposed to the healthy function of the duodenum by a torpid state of bowels is to be corrected by yielding a ready obedience to the calls of nature, and by endeavouring to establish an habitual evacuation by visiting the water-closet every morning after breakfast; by the use of the tepid water lavement morning or evening; and, failing these, by the use of the mildest aperients. According to our experience, those of which aloes forms the chief ingredient are the best. It may be combined with rhubarb, guaiacum, soap, and a small quantity of ipecacuanha, or James's powder; and in case of flatulence, with the pil. galban. comp. according to the formula already given. The aperient pill appears sometimes to be more efficacious and less injurious when taken with dinner. A convenient formula given by Dr. Yeats is the following:—

R Infus. anthem. ℥i.

Vini aloes 3i.

Liquor. potass. gr. xv.

Fiat haustus mane sumendus. But he prefers a combination of senna and quassia, viz.

R Lign. quassiae ℥i.

Fol. sennae ℥i. ad ℥iii.

Aquæ lbi.

Fiat infusum.

R Infusi ℥i℥.

Potassæ sulphatis ℥i.

Fiat haustus mane et meridiè sumendus.

As soon as possible, attempts should be made to discontinue the use of these artificial means, for a constant recurrence to any aperient me-

dicine is sure to establish ultimately a more permanent disease of the intestines.

3. Besides the means for fulfilling the last indications, all directly tending to correct the morbid condition of the duodenum, those which have the power of improving the tone of the alimentary canal in general, or the whole system, possess to a certain degree this power. Amongst the first we have seen the nitric acid in decoction of sarsaparilla or some light bitter infusion most advantageously used. Amongst the latter we may specify the cold ablu-tion of the surface, the shower-bath, the nitro-muriatic acid lotion, and assiduous friction with the coarse flannel glove. But in obstinate cases we have found the most effectual remedy in a course of alterative aperient waters, as those of the Muhlbrunnen of Carlsbad, either natural or artificial; more especially if (which is not rarely the case) this disordered function of the duodenum be engrafted upon, or be the result of, a general state of excrementitious plethora.

II.—*Inflammatory duodenal dyspepsia.*

Synonyms.—*Phagedæna, Cæl. Aurel.*; hepatitis obscura; hepatalgia infarctus, intemperie calida; aurigo ab obstructione calida; hypochondriasis melancholica, *Sauvages*; hepatitis chronica, *Cullen*; indigestion, second stage of, *W. Philip*; duodenite chronique, *Cazimir Broussais*.

General character.—Heavy dull pain; sense of weight or uneasiness in the right hypochondrium, confined to one point, or more generally diffused, more or less constant, but varying in degree, being sensibly increased a certain time after taking food, and in some degree subsiding as the process of digestion is finished; skin dry; extremities cold; but increased heat of surface during sleep, particularly of the palms of the hands and soles of the feet; complexion sallow; countenance dejected; urine scanty, high-coloured, and depositing a lateritious sediment; tongue more or less furred behind, of a glossy red colour at the point and margin, the redness being either bright, equal, or continuous, or brighter red points are dispersed over the general redness, or the papillæ unusually red, large, and developed, sometimes tuberosæ.

The form of dyspepsia which we are anxious to specify by the foregoing character, has been merged in the description of the diseases of organs considered more important, and whose functions were better known. By Hippocrates it was comprehended under atrabiliary affections; by Celsus and Aretæus it was not distinguished from the diseases of the liver or the disorders of the stomach; by the Methodists its symptoms were distributed amongst several diseases. The moderns have been misled by the same errors. Sometimes confounded with other diseases, we may find it under chronic hepatitis or hepatalgia, or, undue importance being attached to some of its symptoms, it assumes the name of gastrodynia or icterus, but still more commonly we may detect it under the mask of hypochondriasis or melancholy. Of the pathological condition which

constitutes the disease Cullen had a proper conception, and evidently includes it under *enteritis erythematica*; but he does not seem to have ascertained the symptoms of this particular disease, for he has no where described them except under chronic hepatitis. The disease is well described by Dr. Ferriar, of Manchester, who had himself been the subject of it, and was by him distinguished from diseases of the liver. Dr. G. D. Yeats followed up the observation of Dr. Ferriar with a spirit of practical and scientific inquiry; but it is to Dr. Wilson Philip that we are indebted for the full development of the nature of this disease and the distinct knowledge we possess of it, though we can by no means subscribe to the limitations by which he has defined its origin, or to the latitude which he has allowed to its issue.

Form of disease.—The derangement of the function of digestion which arises from an excited state, from increased vascularity, or from chronic inflammation of the mucous membrane of the pylorus and duodenum, is by no means a rare species of dyspepsia, and, although manifesting itself by a great variety of symptoms, is in no degree difficult of detection. Its symptoms are either direct, indicating the seat of the disorder, or indirect, shewing the full and various play of sympathy by which the different parts of the body hold communication with each other. Of the former kind are the dull heavy pain, the sense of weight, of anxiety, or uneasiness, which, sometimes commencing in the epigastrium, is generally seated in the right hypochondrium. This uneasy feeling is either confined to one circumscribed point, or it is diffused over the whole hypochondrium; sometimes it extends from the epigastrium round the right side to the spine like half a zone, giving the feeling as if the side were begirt and compressed by a sickle; often the course of the pain traces with anatomical accuracy the course of the duodenum downwards, and backwards in the direction of the right kidney, and then again inwards towards the umbilicus; very frequently the pain extends directly backwards under the right scapula. The uneasy feeling of the right hypochondrium very often corresponds with pain of the right acromion, of the upper part of the right arm, elbow, or wrist, or with a feeling of weakness or numbness of the whole arm; occasionally it extends down to the thigh, to the knee, right leg, or ankle, giving rise to some topical pain in this extremity, or to a more general dull pain or sense of numbness, so that the whole right side of the body feels weaker than the left. When digestion is not in progress, the pain and uneasy feeling of the right hypochondrium is considerably less sensible, seldom amounting to more than a sense of heat, gnawing, or sinking towards the epigastric region, with a frequent desire to take food, which frequently corresponds with a sense of heat, smarting, or blistering of the tip of the tongue, and with watering of the mouth. By complying with this craving for food, relief is for a time afforded, but after a considerable interval, from two to four hours, the uneasy feel-

ings are very much aggravated, in severe cases amounting to excruciating pain, bearing all the symptoms of a fit of gastrodynia, which continues for some hours, then gradually subsides; or which is at other times only relieved by vomiting, generally taking place three or four hours after taking food. The uneasy feeling does not usually amount to actual pain, but is described as a rawness and tenderness, and sometimes as a feeling of heat, as if hot water were passing through the intestine, or there is a painful feeling of distention, especially after meals, though no actual appearance of distension can be perceived. But often there is very sensible fulness in the same situation, extending downwards along the edge of the cartilages of the ribs and through the whole hypochondrium. The part of the right hypochondrium which is the seat of pain or uneasiness is also often very tender, the pain being sensibly increased by pressure, but generally it is not increased, on the contrary it is sometimes relieved by it. This tenderness is perceptible in the epigastrium, but most especially at the pyloric extremity of the stomach, and in the course of the duodenum, in the soft parts close to the edge of the cartilages of the false ribs on the right side; the cartilages themselves often become very tender, not unfrequently more so than the soft parts. This tenderness on pressure, which becomes much more apparent if the effects of pressure of the right and left hypochondrium be compared, like the pain, is very often circumscribed, being generally situated midway between the point of the sternum and the lowest cartilage of the ribs: in the region of the pylorus it is generally more constant, in the region of the duodenum only occasional. The patient is in general quite unconscious of this tenderness until it is pointed out by the physician. But not unfrequently neither pain, uneasiness, nor tenderness is referred to the bowel; but when food has been taken a considerable time, the general uncomfortable feelings of the patient are very much aggravated, the process of digestion being attended with an insupportable languor, lassitude, oppression, dejection of spirits, headach, thirst, fever, or other sympathetic affections.

Amongst the sympathetic affections or indirect symptoms of this diseased state of the duodenum, the affections of the head are most frequent; they are either a general painful confused headach, increased by stooping or by holding the breath, or a dull pain in the back part of the head, which feels tightly bound, or painful pulsation of the head excited by the least effort of attention; vertigo is also a very common symptom. Not rarely the intellectual functions are very much weakened or disordered; there is a general confusion of mind, impaired memory, or deficient power of attention. The external senses become sometimes quite dull, the vision indistinct or veiled with dark motes; the hearing, smell, and taste much impaired. The entire function of the mind not unfrequently becomes disordered, and mania itself we have distinctly traced to local irritation of the duodenum.

Irritation of the larynx, producing a short dry cough, or causing frequent efforts to expectorate a grey transparent mucus, (which sometimes becomes very considerable,) hoarseness, and loss of voice, a sensation of constriction of the chest with laborious breathing, and complete paroxysms of spasmodic asthma, are the sympathetic affections of the respiratory organs which frequently originate in this disease. In protracted cases of this disease it is by no means uncommon for phthisis pulmonalis to supervene, and ultimately terminate the life of the patient. It most frequently assumes the form of laryngeal phthisis, but generally a tubercular affection of the lungs lurks behind. Nor does there seem any difficulty in understanding this issue of the disease; nothing is more comprehensible than that the irritation of the duodenum should be communicated sympathetically to the mucous membrane of the larynx, trachea, and bronchi, or that the cachectic state induced by the long-continued derangement of the digestive organs, should produce the tubercular disease. This conversion of dyspepsia to phthisis was noticed by Dr. Ferriar, but has been only fully explained and insisted upon by Dr. W. Philip* and Dr. James Clark.†

Painful affections of the heart are consequences not less common, simulating the character of hypertrophy of the ventricles, sometimes of angina pectoris.

The urinary and sexual organs frequently feel the effects of duodenal irritation: hence spasmodic stricture of the urethra, painful affections of the testicles, priapism, and venereal dreams; also painful menstruation. Lumbago, painful affection of the hip and knee joints, rheumatism, rheumatic gout, nodosity of the joints, severe and deep-seated neuralgic pains of the legs, we have observed connected with this disease.

Sometimes the skin is the seat of the secondary effects of this disease. We have noticed, in conjunction with it, *herpes zoster*, *acne induratum*, *urticaria*, *lichen*, *psoriasis*, *pityriasis*, and *alopecia areata*.

Inflammatory or spasmodic affections of either extremity of the alimentary canal are common attendants of irritation of the duodenum, such as erysipelatous affections of the fauces, generally with a sense of tickling, soreness, or rawness of the throat. The uvula sometimes becomes much elongated, and, losing much of its contractile power, gives the sensation of something resting on the back part of the tongue, and sometimes descending lower, creates cough, a sense of choking, nausea, and even vomiting, frequently all comprehended under the common term of relaxation of the throat; not rarely the fauces and neighbouring parts are the seat of troublesome ulcerations, which, united with affections of the skin and osteocopic pains, make up the symptoms of pseudo-syphilis. On the other hand, *prurigo podicis*, sometimes accompanied with eruptions in various forms, spasmodic stricture of the anus or rectum, inflammation of the

mucous membrane of the rectum, hemorrhoidal swellings, painful and irritable excrescences and fissures, are sympathetic consequences of this disease.

But whatever be the particular sympathetic affection which may result from the disorder of the duodenum, there is one general and constant which belongs and gives character to them all—hypochondriasis, despondency and dejection of spirits, the mind constantly intent upon and occupied with the bodily feelings.

The preceding complaints, whether direct or indirect, are always attended by symptoms sufficient to indicate that the natural functions of the body are in a state of disorder. Though the appetite may not be deficient, it is seldom natural; it is various and capricious, generally keen, craving, not rarely ravenous; there is a sense of sinking, of gnawing, or a constantly recurring desire for food, only temporarily relieved by taking it; or an uneasy sensation, or craving, mistaken for hunger—*mendax fames, cibi, appetentia, corpore non indigente*. Bulimia is sometimes a symptom of duodenal irritation, corresponding to the *phagedæna* of Cælius Aurelianus, which we have accordingly not hesitated to place among the synonyms of this disease. There is no particular thirst. The bowels are habitually confined; under the use of animal food they are more costive; with a vegetable diet they are frequently disposed to be relaxed; a fit of bilious diarrhoea from time to time is not however a rare occurrence; and an habitually loose or irritable state of bowels is sometimes observed, a dejection following soon after a meal; purgatives also occasionally act in small doses, but frequently with aggravation, instead of relief, of the symptoms. In this state laxative medicines are generally uncertain in their effects, and frequently apt to act too violently. The evacuations present great variety in their appearance; they are not always different from those of health; sometimes they are perfectly natural, but generally mixed with mucus in a concrete tenacious state; more frequently they are scanty, adust, and hard, in small knots of a dark blackish green, frequently of a dark olive green, sometimes of a blackish brown colour; they are frequently smeared with mucus and deficient in smell; occasionally two or three dark fetid stools are discharged, small in quantity without being figured; or there is a loose stool of a greenish brown colour, in smell resembling the grounds of sour beer, which is often preceded by great depression of spirits; not rarely they are like tar. Generally they are too dark, and occasionally almost black, but frequently they are of a white clay colour; sometimes there is frequent purging of a substance like the whitest pipemakers' clay, more or less diluted with water; which state has been known to occur when dissection proved the liver to be free from disease, and the gall-bladder containing healthy bile. The urine is scanty, high-coloured, sometimes of a dark copper colour, or even opaque, and as dark as mahogany or porter; it always reddens litmus paper, and generally deposits a lateritious sediment. The tongue is smooth, or covered with a thin loose mucous fur towards the root,

* Op. cit.

† Influence of Climate, &c.

of a clear red colour, neither a bright nor a pale red; but its anterior part is spotted with small red flat spots of a darker or brighter red colour, not rising above the level of the surface of the tongue, the papillæ being very small or very indistinct; or the whole surface of the tip of the tongue and anterior margin is unusually red, with some of the papillæ more or less enlarged; and in this situation there is frequently a sense of heat, smarting, or of blistering, frequently distinctly corresponding with the uneasy sensation in the right hypochondrium. The tongue is always more or less furred towards the root, either with a thin shining coat anteriorly, or clean and moist. The lips always correspond with the state of the tongue; they are of a glossy red colour, or their cuticle is dry and exfoliatory. In protracted cases the lips grow dry, and are divided by fissures: the tongue is covered with a rough yellowish crust, brown towards the root; in some cases there is a peculiar raw appearance of the tongue and throat; at other times the tongue presents a peculiar red, dry, and glazed appearance.

The skin is generally dry and scabrous, sometimes scaly almost to ichthyosis; the complexion is dull and sallow, and the conjunctiva has invariably a tinge more or less of yellow. The pulse is either quicker than natural, or easily accelerated, but seldom ranges habitually above eighty. In the quality of the pulse there is always perceptible a certain degree of hardness or rather tension, which, according to Dr. W. Philip, is in its slighter degree easily detected, in feeling the pulse, by gradually diminishing the pressure of the finger. On some occasions it is very quick and small, but always with a certain degree of tightness, the most certain measure of the general state of the secretory surfaces. The temperature of the body is very variable and unequally distributed; sometimes there is considerable fever or feverish heat; sometimes chilliness independent of any change of temperature of the surrounding medium, at times interrupted by fits of oppressive heat; during the day the hands and feet are often obstinately cold, but after eating and during the night the palms of the hands and soles of the feet often become preternaturally dry and hot, and there is a tendency to partial heavy sweats, sometimes very profuse during sleep, more especially towards the morning. And not unfrequently there is a feeling of a slight but protracted feverishness when the pulse is not at all affected.

Pathology and etiology.—That the symptoms we have just described are all referable to different degrees of increased vascularity, sometimes to inflammation of the mucous membrane which lines the pylorus and duodenum, there is little room to doubt. It has been directly proved by numerous dissections; it has been confirmed analogically by cases of organic disease of this part of the alimentary canal, where the pathological condition gave rise to increased sensibility of the mucous surfaces, as in ulceration; the nature of the remedies most usually giving relief afford strong confirmation of this opinion; and, were

more direct proofs wanting, it is the only hypothesis capable of rendering a satisfactory explanation of the symptoms. For if we consider the nature of this pathological state of the mucous membranes, the various degrees in which it exists, the particular part of these organs in which it may be seated, whether above or below the termination of the common gall-duct, whether it may affect the whole mucous tissue, or confine itself to the follicles or to the villousities, and, lastly, the extensive sympathetic relation of these organs, by which the irritations of their morbid conditions may be felt and reflected, we shall be furnished with abundant elements from whose combinations it will be easy to explain all the variety of symptoms, direct and indirect, primary and secondary, constant and accidental, which the disease presents. We shall thus understand how the appetite, if there be no fever, instead of being impaired, is generally increased, sometimes keen and ravenous, though the bowels are habitually confined, knowing it to be the nature of the alimentary canal to have its peristaltic motion increased towards any point situated below, and diminished from any point of irritation situated above; how the erythematous state of the mucous membrane of the duodenum, disordering its peristaltic motion, may impede the flow of bile, and may in different ways derange the functions of the liver; how the secretion of bile, generally diminished, may be sometimes increased when inflammatory irritation exists about or below the orifices of the biliary ducts, thus leading to bilious diarrhoea, to imperfect *encholosis*, and all the variety of alvine evacuation; how an inflammatory action of the duodenum, even when existing only in a slight degree,—so slight as to elude the closest observation unless the mind be attentively directed to it,—may excite the liver to an unhealthy action, from which a state of *erethism* and irritability of the whole alimentary canal may ensue; and hence how purgatives act so irregularly;—or, on the contrary, how the vascular injection of the mucous membrane of the duodenum, being the effect of a sanguineous congestion of the liver, by which its freedom of circulation and its secretion is suppressed, may be attended with a diarrhoea in which the alvine evacuations are of a light colour; and how a particular form of jaundice (*icterus à plethorâ*) may be produced. The well-known sympathies of the different parts of the alimentary canal with each other, supply the means of accounting for the appearances presented by the throat, the mouth, and the tongue, and for the uncomfortable and painful symptoms which sometimes take possession of the other extremity of the canal; and the universal consent of the state of the alimentary canal with the body in general, or with some organs in particular, explains the multifarious secondary affections which may supervene upon this disease.*

* For a full account of the sympathetic relations of the duodenum with other parts of the body, the reader may consult with advantage Dr. Yeats' excellent paper, *Med. Trans.* vol. vi.

Nor does it seem more easy to explain the symptoms of this morbid condition of the mucous membrane of the duodenum than to account for its production, if we consider the operation of the causes in which it originates. Thus it is that atonic gastric dyspepsia long-continued, (by which as it were the stomach shifts its function upon the duodenum, the pylorus being irritated by the passage of substances imperfectly digested, and the duodenum, instead of receiving a substance of the bland nature of chyme, becomes the receptacle of the crude residuum of an imperfect digestion,) is observed to prepare the way for this form of dyspepsia, and frequently to terminate in it—more rarely to be relieved by it. In the same manner, though the function of the stomach may not be imperfectly performed, if persons indulge in the use of substances which no power of digestion can assimilate, (as unripe fruits, crude vegetables, the seeds and skins of fruit, the kernels of nuts and stone fruit,) the operation and the consequence will be the same. And in like manner, when sufficient time has not been allowed for the digestion of one meal before another is taken, the duodenum becomes unnaturally distended, from which irritation and an inflammatory state of the mucous membrane may arise,—a circumstance which, occurring frequently in children, inducing a saburral state of the mucous membranes amounting to inflammation, constitutes the preparatory process to the particular remittent fever which afflicts that period of life. But from whatever cause gastric or intestinal fever may arise, chronic inflammation of the mucous membrane is one of their most constant sequelæ; and we must confess that our experience knows no cause of this form of dyspepsia more common than improper diet in the convalescence of those fevers. In persons habitually subject to dyspepsia, which naturally predisposes to irritation of the mucous membranes, an inflammatory state of the duodenum may arise from suppressed perspiration, from exposure to cold, particularly in dry weather, either hot or cold, as is frequently observed in the spring; and in the same way it is a common sequel of catarrh, and a frequent consequence of the retrocession of eruptions of the skin. But of all the causes capable of inducing this morbid condition of the duodenum, there is undoubtedly none more sure, and none more general, than the injudicious use of medicines in the treatment of other forms of dyspepsia, in which irritating drastics, heating tonics, and stimulants are lavishly and uninterruptedly applied to delicate and sensitive membranes either already inflamed, or which they seldom fail to make so.

There is also another source of this disease which deserves notice, where it presents itself as a secondary affection, the consequence of a state of plethora or congestion of the vena portarum, from which results vascular injection of the mucous surfaces, giving rise, under irritation, to inflammation of a subacute or passive form, *dyspepsia hemorrhoidalis*;* and also a corresponding form of disease which arises from

plethora of the uterine system, where the menstrual relief has been insufficient, *dyspepsia dysmenorrhæa* and *amenorrhæa*.* Upon this state of disease it is not uncommon for menorrhagia from time to time to supervene. The irritation of teething in children, from some sympathy, direct or indirect, with the liver, the bile being suppressed and hepatic plethora induced, not rarely induces the morbid condition of the mucous membrane which constitutes this disease, *dyspepsia dysodouriasis*. Hence the light-coloured evacuations, and hence the discharges of blood, in short the dysentery of infants in dentition.

Treatment.—The method of cure of this species of dyspepsia naturally divides itself into the following indications: 1. to correct the morbid condition which constitutes the disease—to remove the vascular excitement or inflammatory state of the mucous membrane lining the pylorus and duodenum; and 2, to render the function of digestion easy of performance, by which the causes of the disease will be avoided.

1. The principle of this indication must necessarily be antiphlogistic; but its application requires nice and delicate modifications and adjustments to ensure its success, or the physician may plunge his patient into a state of depression which will frustrate his intentions. General bloodletting is seldom necessary; but if there be signs of general plethora, if the pulse be hard, tense, and resisting, if the pain of the right hypochondrium be severe, with much heat of surface, and much heat and dryness of the mouth and redness of the tongue, a small general bloodletting will be found to be the means which affords the most speedy and most permanent relief. It spares the necessity of topical depletion, and renders a much smaller quantity of medicine necessary, facilitates its action, and ensures its effect. When the symptoms indicate a state of plethora of the abdominal circulation, such as a full or varicose state of the veins of the lower extremities, swelling of the feet, pain in the loins, more especially in the sacrum, indicative of a hemorrhoidal disposition, dark-coloured or sedimentous urine, a large tongue, seemingly swollen with blood, and eruptions of the skin, the congestion is more speedily subdued, and with less expense to the constitution, by very small bloodlettings, repeated at intervals of a fortnight, than by any other method; and the result is easy of explanation—it seems as if the quantity taken away from the general circulation were supplied from the circulation of the vena portarum, by which the congestion is diminished, and freedom given to the passage of the blood in the hepatic system. Where neither of the above-mentioned states is present, the local detraction of blood from the tender part of the epigastrium or hypochondrium by leeches or by cupping, to the amount of from four to twelve ounces of blood, according to the circumstances, will be found to satisfy the object of this indication; but if after a few days the symptoms do not indicate improve-

* Cullen.

* Id.

ment, it must be repeated. Except in nervous, irritable, and easily excitable persons, it is often of general service and sometimes very successful to endeavour to induce a derivation of blood upon the hemorrhoidal vessels by the application of leeches to the margin of the anus. The antiphlogistic effect of both general and topical bloodletting may be increased, and rendered more durable by the various methods of counter-irritation and derivation to the skin. For this purpose we think the tartar-emetic ointment or plaster is much to be preferred to blisters; but these also are occasionally useful. In old and protracted cases we have known the greatest comfort derived from the long-continued use of a warm plaster, gently stimulating, sufficiently large to cover the whole hypochondrium. In cases where the obstinacy of the complaint justifies it, either yielding with difficulty or frequently recurring, no method of counter-irritation is to be compared to a seton, from which the most permanent good results are frequently obtained: it should be introduced obliquely in the direction of the cartilages of the false ribs.

In aid of depletory means, or where the degree of the symptoms have not called for them, considerable benefit may be derived from certain medicines which have a direct antiphlogistic effect upon the mucous membranes of the intestines. These, according to our experience, are castor-oil, nitrate of potass, antimonial, and vegetable acids. The castor-oil should be given in doses of a drachm, repeated once in the twenty-four hours; it is best given at bed-time for its soothing and antiphlogistic effect upon the mucous membrane; but in the morning, if its aperient action is desired. In inflammatory irritation of the pylorus and duodenum it is a most valuable remedy, often by its soothing effect acting like an opiate, and has the most direct and the most remarkable power in allaying and relieving a heated state of the mucous membranes of the pylorus and duodenum. We must confess that we know no medicine more eminently endowed with this property. In obstinate chronic cases of this disease, we have known a small tea-spoonful of castor-oil taken every night at bed-time, as long as the stomach could easily bear it, a remedy attended with the most signal success. The effects of the castor-oil upon the stomach afford a very good test of the nature of the morbid condition of its mucous membranes. In atonic dyspepsia it is borne with the greatest difficulty, producing nausea and vomiting; in purely irritable dyspepsia a small dose of castor-oil acts severely and with much griping; but if there be any degree of vascular excitement of the mucous membranes, it soothes and quiets, and its effect is often most useful in this way when it has no aperient action. Its good effects will not be frustrated by administering it in any mild carminative water, in emulsion, in coffee, or by combining it with a little liquor potassæ. The nitrate of potass given in repeated small doses is a useful medicine, and of considerable power in correcting the vascular excitement of the mucous membranes. It may be given in doses of from five to ten grains three times

a day, in an ounce of water, to which a very small quantity of mucilage of gum arabic has been added. If there be much thirst, the nitrate of potass may be given in a saline draught; and if there be great irritability or restlessness, it may be combined with a small dose of the tincture of hyoscyamus, of lettuce, hop, or conium; if there be much dryness of the skin, it may be combined with a very small dose of vinum ipecacuanhæ, or Dover's powder. When the cold or atonic state of the stomach tolerates with difficulty the nitrate of potass, or as the symptoms subside, it may be exhibited in some bitters, as infusion of chamomile, quassia, or orange-peel, to which a very small quantity of spiritus ætheris nitrici, tincture of cardamom, or orange-peel, has been added: tartarised antimony in very small doses, as small as one-twelfth of a grain, may be given with the same intention as the nitrate of potass, and, by determining to the skin, sometimes more efficiently. It may be given in various vehicles, which, acting as modifying agents, adapt it to the particular circumstances of each case, as in saline draughts, orange-flower water, camphor julap, infusion of quassia, and such-like.

In a highly irritable state of the alimentary canal small doses of colchicum or hydrocyanic acid are frequently of signal service, and may be combined in the same way as the nitrate of potass and tartarised antimony.

The general effect of these antiphlogistic means will be very much promoted by the use of the fresh-water or sea-water tepid bath, daily, or every alternate day.

The intention of this indication will also be indirectly fulfilled by those means which, promoting the healthy secretion of bile, give freedom of circulation to the liver; and therefore, not before, but after depletion suitable to the case, and in aid of and combined with the means above specified, recourse must be had to hepatic alteratives, chiefly mercurial medicines, which require great care and discretion in their use. The pil. hydrargyri is in general the most suitable form of this medicine; if the bowels are irritable, or if there be a disposition to diarrhœa, the pulv. hydrargyri cum cretâ is to be preferred; if the bowels are extremely sluggish, calomel. In recent cases it is most advisable to give five grains of pil. hydrargyri, or three grains of calomel; in protracted cases, small and repeated doses are to be preferred, one grain, sometimes half a grain of blue pill two or three times a day, the object being to obtain the action of the mercury upon the liver without irritating the mucous membranes. We think it better to give the medicine continuously until the secretion of the bile is improved, than interruptedly, thus keeping the body longer under the irritation of the medicine. When the mercury appears to be exciting the mucous membranes without promoting the secretions, which will be known by the increased redness and dryness of the lips and tongue, it may be prudent to interrupt the use of the medicine from time to time. The mercurial may be advantageously combined with other medicines, to modify and

facilitate its action; as with small doses of the antimonium tartarizatum, or of the pulv. ipecacuanhæ, when it is desirable to influence the secretion of the skin; with nitrate of potass, pil. scillæ comp. to favour the action of the kidneys; with extract. aloes to promote the action of the bowels; with extract. hyoscyami, extract. conii, or extract. papav. if there be pain or restlessness; with pil. galban. comp. if there be flatulence or hysterical symptoms; and with any bitter extract or aromatic confection, if it oppresses the stomach. We have seen no advantage in this complaint from the inunction of mercury, and have found it less easy to regulate its action in this way; besides, it thus affects the whole system unnecessarily; and the advantage of mercury in this complaint being chiefly derived from its local action upon the liver, anything more is pernicious, and whenever the least sign of salivation appears its use ought to be discontinued.

The use of mercury will be very much assisted by taraxacum, a medicine which has also a very sensible effect in soothing the mucous membranes; and in mild cases this last will alone suffice. When given in an efficient formula, it is a most valuable remedy in this species of dyspepsia. The extract may be given in infusion of hop, chamomile, or orange-peel, in the compound decoction of sarsaparilla, and in nervous patients in camphor julap, to which may be added, according to the intention, a small quantity of nitrate of potass, of sulphate of potass, of compound decoction of aloes, or spiritus eth. nitrici.

R. Ext. taraxaci, ʒii.

Potassæ nitratis, ʒʒ.

Spiritus eth. nitrici, ʒi.

Infus. cort. aurant. ʒvi. M.

Cochleare amplum bis terve die sumendum.

The nitric acid, nitro-muriatic acid, and the solution of chlorine, are also useful auxiliaries after mercury, in some cases substitutes for it. They may be used internally in decoction of liquorice, or compound decoction of sarsaparilla, to either of which a little spiritus æth. nitrici may be added; or they may be used externally either in the form of bath or lotion. In case of diarrhœa supervening, their use should be immediately suspended.

2. This indication will be fulfilled, *a.* by a proper regulation of diet, suited to the degree of the complaint; *b.* by preserving an open state of bowels; and *c.* by assisting the function of digestion by mild tonics, and by proper air and exercise.

a. In the slighter degrees of this complaint very low diet is seldom necessary; a little mutton or chicken may be taken daily, or every second day, and is preferable to a diet consisting exclusively of farinaceous food. In other respects it should be light, bland, and cooling, and in small quantities at a time: light refreshing broths or soups in moderate quantity, light puddings, arrow-root jelly, rice-gruel, blancmanger of rice or semolina. In some forms of this disease it is sometimes necessary to restrict the patient wholly to a fluid diet, to jellies of amylaceous and farinaceous

food, gruel, asses' milk, and jelly of Iceland moss. In ordinary cases the stomach requires a certain quantity of animal food, and in this species of dyspepsia the fat of animal food, particularly the fat of bacon, is more easily digested than the lean; and it appears besides to have a useful effect in allaying the irritation of the mucous membranes, and in assisting the action of the bowels.

In severe cases, where there may be a disposition to feverishness, any increase of heat of surface, thirst, or night perspirations, it is advisable to abstain from wine. It must at all times be taken in very limited quantity, and its use from time to time interrupted, but it need not be wholly abstained from, and the digestion is very frequently promoted by it. Seltzer water is the best beverage in this complaint; but we have not found any inconvenience from light table-beer in small quantities.

b. The warm or cold water lavement is the best means of preserving an open state of the bowels. If this does not succeed, or cannot be used, castor-oil may be given in small doses night or morning; its aperient action may be assisted by combining it with manna, or a pill formed of pulv. aloes comp. two parts, and soap one part, may be used instead.

c. The process of digestion may in some degree be facilitated and assisted by light bitters, as the infus. quassiae, calumbæ, or cort. aurant. to which some neutral salt, as the nitrate or sulphate of potass, may be added in small doses; by the mineral acids, as the phosphoric, the aromatic sulphuric acid, or nitric acid in small doses; or by the cautious use of wholesome wine in small quantities. But the means which restore the tone and strength of the body in general are far preferable. These are proper exercise, neither heating nor fatiguing, as horse exercise, or a sea voyage; dwelling much in the open air, in a dry open air; change of air and place; cold abluition with vinegar and water; proper clothing, warm but not oppressive; and gentle occupation of the mind; all which remedial measures have been already sufficiently noticed.

We must not, however, omit to mention the use of mineral waters in the treatment of the chronic form of this disease, which combine the means of at once fulfilling all the foregoing indications, and render it difficult to know under which head to class them. The most efficient of these according to our experience are the Kreuzbrunnen of Marienbad, and the sulphureous waters of Harrogate. They may be taken warm or cold, as best may suit the sensibility of the stomach, its power of digesting or absorbing them. Their action should as soon as possible be derived on the bowels, and they ought to be continued until the healthy function of the bowels has been restored, and until the tongue has lost its heated and red aspect, and assumed a healthy appearance. In order to render their good effects more permanent, their dose ought to be gradually diminished. A course of goat's milk or whey drunk every morning in considerable quantities, has been known to have a similar effect. In Scotland

and in Switzerland it is frequently had recourse to; and we heartily join the late Dr. Ryal in his earnest wishes that an establishment for the supply of goat's whey were formed upon our Brighton Downs, which afford every means of doing so, and where the adjacency of a large town promises a ready consumption. We are inclined to think that the disorders of the liver in which it has been found to be so useful, have been only forms of inflammatory duodenal dyspepsia.

Though the treatment of the primary disease has only occupied our attention, we do not think that the secondary or sympathetic affections which originate in it should be wholly left to depend upon it. We think, whenever symptoms can be relieved without interfering with the general plan of treatment, it is always useful, and ought always to be attempted. As has been correctly observed by Dr. W. Philip, the secondary affections undergo the same change and partake of the same nature with the disease from which they spring; therefore the secondary affections in this disease are apt to assume an inflammatory character, to become more and more of a permanent nature, in the same proportion more independent of the original disease, and, on that account, more demanding the physician's careful attention. But with this passing observation our limits oblige us to leave them to be each considered under its proper head.

Strumous dyspepsia.

Under this title we are anxious to draw the attention of the profession to the form of dyspepsia which belongs to the scrofulous constitution, for in our opinion it presents a more characteristic feature of this habit of body than any physiognomical portrait which has yet been drawn of it. In this respect it is more to be depended on than either the fine skin, the clear delicate complexion, the light hair, large blue eyes, and dull scleroticæ of one variety; or the foul, dull, swarthy-coloured skin, the sallow complexion and swollen countenance, the dark hair, and tumid upper lip of the other. It betokens, indeed, little familiarity with scrofula to connect it with any particular temperament, for it belongs to all temperaments, to the sanguine as well as the phlegmatic, to the nervous as well as the melancholic, and to all their varieties and combinations. But upon whatever temperament the disordered habit which we call scrofula may engraft itself, we venture to say that this form of dyspepsia will also there be found; and, therefore, being constantly present with it, preceding and accompanying the various symptoms which issue from it, it would be contrary to all reason to refuse to it an important share in the development of this disordered habit, and in the production of the local affections which have hitherto too much engrossed the attention, to the exclusion of a proper consideration of the constitutional disease.

Of late years, however, the constitutional affection has received more of the notice of physicians. It has been described by Malfatti of Vienna under the name of *latent scrofula*,

by Dr. Ayre under that of *chronic marasmus*, and most faithfully by Dr. James Clark under the term *tubercular cachexy*; it has also been sketched by Dr. Marshall Hall under the title of *disorder of the general health in tuberculous affections*; but we are not aware that any of these physicians have connected it with a special disorder of the chylipoietic function.

Form of the disease.—In the offspring of scrofulous and also of dyspeptic, hypochondriacal, or cachectic parents, in the children of old men, in children who have been badly nursed, or who, brought up by hand, have been improperly fed, or reared in the impure air of crowded towns, symptoms of disorder of the function of digestion early manifest themselves, generally between the first and tenth year, often commencing with the first dentition, which is commonly painful and difficult. Though the child from time to time loses its appetite, it is generally morbidly craving or ravenous, even soon after a plentiful meal requiring fresh food, so that the nurse remarks there is no satisfying such children. The complexion loses its colour, the skin its tone, ceasing to compress the flesh; the flesh becomes soft and flabby, the appearance is languid, the belly generally tumid, and there is a want of the usual disposition to play, or to use the exercise common to that period of life. The little patient is soon tired, complains of aching of the legs and knees, desires frequently to be taken up; his temper is fretful, he is easily set a-crying, and his intellect is either precocious or unusually dull. His sleep is seldom calm and composed; he moans, talks, or grinds his teeth, sometimes screams and raves. His bowels are generally confined, and his evacuations are of a light grey colour, like pale brown paper, sometimes curdled with streaks of mucus; or they are of a greenish colour, frequently yeasty, of a sour and highly offensive smell, and very often the food is passed unchanged. Diarrhœa occasionally occurs, consisting usually of light-coloured or slimy stools, and the patient frequently complains of pain in the bowels or uneasiness of the stomach. The urine often deposits a whitish sediment; the breath is fetid or heated; there is some slight thirst, slight heat of skin, except on the extremities, which are colder than natural; the skin is harsh and dry, except during sleep, when there are frequently heavy but partial sweats. The tongue is redder than natural, and on its anterior part spotted with small points of a darker and brighter red colour than the general surface; it is seldom much furred, being either covered with a thin mucous fur, through which the red spots appear, or with a slimy brownish coat, or the fur is distributed in small circular white spots, more or less confluent, presenting altogether a dappled appearance. When irritation of the stomach supervenes, the tongue is dry and of a brownish red colour. These symptoms, seldom entirely absent, continue from time to time to recur, more or less severe in degree, as the causes of derangement, irregularities in diet, an indulged and pampered

appetite, may present themselves, being always most remarkably manifest after any of the ordinary diseases of childhood. As the child grows, unless the most judicious management has interfered with the natural progress of the complaint, other symptoms begin to appear. The patient becomes subject to sore throat, the fauces are redder than natural, and the tonsillary glands are observed to enlarge; there is a frequent tickling cough, and itching and picking of the nose and lips. The hands and feet are usually very cold and damp, or on the least cold turn of a dark livid purple colour, and the child is extremely subject to chilblains, even sometimes in summer. The patient is liable to be troubled with various affections of the skin, very early with *porrigo furfurans*, *psoriasis guttata*, *achorous* pustules on the hairy scalp, (the *tinea mucosa* of Alibert,) with *pityriasis*, *herpes circinnatus*, with *lichen* and *purpura*, frequently the *lichen urticans* and *purpura urticans*, at a later age *ichthyosis*, *pityriasis versicolor*, *porrigo decalvans*, *erythema nodosum*, and *porrigo favosa*, sometimes spreading over the whole body, and at a still later period of life, *acne indurata*, one of the most characteristic signs of this habit of body. All these diseases of the skin, in their external appearances so dissimilar, have yet in their nature a close affinity to each other, and, frequently convertible into and succeeding each other, seem only different external manifestations of the various degrees and modifications of the irritations of the internal organs. The eye is frequently the seat of various troublesome affections; hordeola constantly recurring, inflammation or purulent discharges from the ciliary glands, falling off of the eye-lashes, &c. Occasional discharges of blood from the bowels, epistaxis at a much earlier age than usual; copious mucous discharges from the bowels, sometimes from the vagina, are not rarely observed in this disease. Sometimes the cellular system feels exclusively the effects of the internal disease, a succession of cold indolent abscesses occupying every limb of the body. Frequently the nervous system is the seat of the secondary irritation, sometimes in its membranes and vascular structure, giving rise to inflammation and hydrocephalus; sometimes in its functions, inducing chorea, epilepsy, idiocy. The bones very commonly manifest symptoms of disorder, but the ordinary termination of the disease is the formation of that morbid growth or deposit well known under the name of tubercle, which, most usually seated in the lymphatic glands, has almost exclusively received the name of scrofula.

In young females about the age of puberty this disease frequently undergoes a remarkable change; for habitual constipation becoming established, another form of dyspepsia is induced, which in this constitution very frequently leads to spinal affections.

In the adult age the symptoms present considerable modification. The patient's complexion becomes pale, of a slightly blueish or leaden colour, particularly under the eyes; in dark complexions it becomes of a pale sallow or yel-

lowish colour; the body is more or less emaciated, the skin flaccid, the muscles flabby; there is an unusual sensibility to cold, the patient is very apt to shiver, and there is a constant tendency to coldness and lividity of the extremities. The appetite continues good; frequently it is craving, and the food does not appear to satisfy; sometimes there is a constant empty and sinking feel at the stomach, only temporarily relieved by eating, the patient feeling after a meal as if he had long fasted, and is again desirous of taking food. The bowels are confined; more rarely they are loose, discharging copious light or drab-coloured stools, which are frequently more than usually fetid. The urine generally deposits a whitish sediment, sometimes mucus. The tongue is red at the point, generally studded with enlarged papillæ, of a brownish red colour behind, but seldom coated. The pulse, always weak, is small and drawn, sometimes it is slow and weak. The sleep is seldom natural, the patient is restless during the first part of the night, and towards morning falls into a heavy unrefreshing sleep, during which he sometimes perspires profusely. He is listless and drowsy by day, and though the spirits are sometimes sufficiently cheerful, more commonly the patient is timid, nervous, torpid, or hypochondriacal. Frequently there is a great tendency to perspiration on the least exertion or the least excitement, and the palms of the hands and soles of the feet feel damp and clammy, frequently cold. The thyroid gland, the lymphatic glands of the neck and groin, are observed to be large and swollen, but not painful. In women, leucorrhœa, painful or deficient menstruation, in men, a disposition to hemorrhoids, is observed; but the usual progress of the disease is to *tabes mesenterica* or *phthisis pulmonalis*.

Pathology.—The phenomena of this disease, its whole complexion and character, sufficiently indicate a congestive state of the hepatic system; and were we to assume as the proximate cause of the disease a plethora of the vena portarum, both in its roots and branches, we should be furnished with the means of explaining all the symptoms of the disease; for we should readily understand how, in this state of the circulation of the abdomen, the mucous surfaces of the intestines should be full of blood, consequently subject to inflammatory irritations and disordered functions, whilst the peculiar office of the duodenum renders it especially liable to be the seat of them; how the function of the liver being deranged, all the other consequences of this disease may follow; for though we may not know precisely what share the function of the liver may have in the process of sanguification, we may easily understand how it may interrupt and interfere with this process, leading to a cachectic state of the fluids, from which result tubercles and other semi-vital and semi-organic productions.* Nor

* For a further explanation of this opinion, we refer the reader to our account of the formation of tubercles in Dr. Clark's work on Climate.

does it seem an improbable supposition that a disposition to abdominal plethora, or an organization which favours it, may be transmitted by parents to their offspring, more especially in dyspeptic and hypochondriacal persons, in whom the chylipoietic viscera, under constant irritation, are necessarily also in a state of congestion: we might thus explain how the strumous cachexy is continued, and how it is generated.

The foregoing view of the nature of this disease is also in conformity with the observation and opinions of other physicians. "In children," observes Dr. Wilson Philip, "the symptoms of inflammatory dyspepsia supervene early, and the disease in them commences in the liver rather than in the stomach." And Dr. Ayre has, in the following passage, confirmed our statement, though we have offered another explanation of it: "Diseased mesenteric glands occur in children from acrid condition of the duodenal contents; the liver, pancreas, and duodenal glands become diseased from congestion, and irritation will be propagated to the brain, giving rise to hydrocephalus, spasms, convulsions, vomiting, contortions of the countenance, affections of the sight, violent headaches, faltering voice, chorea, palsy."

Treatment.—The plan of cure of this disease consists in the following indications: 1, to correct the morbid condition of body which we have stated to constitute the essential foundation of the disease; 2, to render the function of digestion easy of performance by a regulation of diet suited to the nature of the disease; and 3, to improve the general tone and strength of the body.

1. In the ordinary degree of this disease it is seldom necessary to relieve the congestive state of the liver by the detraction of blood; but when there is much febrile excitement, with a red and dry tongue, with fulness or tenderness of the right hypochondrium, the application of a few leeches brings more immediate relief, and spares the necessity of much physic. In general the direct antiphlogistic part of the treatment is accomplished by a light diet, by the nitrate of potass given in repeated small doses, either in saline mixture or in some carminative or bitter infusion, as the case may admit, whilst the intention of this indication is also obtained indirectly by increasing the secretion from the liver. We entirely agree with Dr. W. Philip in his high estimation of this remedy, the nitrate of potass. Of itself partly a substitute for mercury, when combined with it, it renders less mercury necessary; with purgatives, it renders their action more free, and with antimonium tartarizatum it is invaluable in case of determination to the head. For promoting the secretion of the liver, mercury is the medicine most usually resorted to; as an occasional remedy for regulating the secretion of the liver, it is also probably the most safe and the most convenient. It should, however, be given only in interrupted doses, and should on no account be allowed to affect the system. The hydrargyrum cum creta combined with a few grains of subcarbonate of soda, and a minute quantity

of pulvis ipecacuanhæ, or pulvis Jacobi, we consider the best general formula. If the bowels are too open, the mercury may be combined with the pulvis ipecac. comp.; if confined, with a little magnesia, nitrate of potass; or extract of aloes; but in either case this alterative should be followed every morning, or every second morning, by a tea-spoonful of castor-oil, by a little electuary of cassia or senna, or by a small dose of sal polychrest. The effects of the mercurial medicine will be also very much promoted by following it up with a course of taraxacum or sarsaparilla, or both united.

The action sought to be induced upon the liver, and through that organ upon the abdominal circulation, by means of mercury, may also be obtained by means of iodine, in our opinion more efficiently and more permanently; and where the inflammatory state of the mucous membrane of the duodenum exists in a slight degree, we think that it merits the preference. We have been in the habit of using the tinct. iodin., and have had much satisfaction in its use in strumous affections, but we have always observed that its value has been invariably in the degree in which it acted on the liver. We have made it a rule to commence in small doses, gradually increasing them; and though we have never seen any untoward consequences from its use, we have invariably observed the precaution of from time to time interrupting its exhibition for a few days. Where there is any hæmorrhagic or scorbutic tendency, shown by eruptions of the nature of purpura, iodine is decidedly contra-indicated. It is probable that the muriate of lime has a similar action upon the liver, and may be advantageously used for this purpose.

In chronic cases we have seen the greatest advantage derived from a course of the Kesselbrunnen of Ems; and when there is any tendency to diarrhoea, we believe it to be preferable to every other form of medicine. The Obersaltbrunnen may be also used in similar circumstances.

When the state of the mucous surfaces admits of the exhibition of chalybeates, they prove an alterative of very great value, and possess considerable power of correcting the congestive state of the abdominal circulation. This property of chalybeates has in our opinion been very much overlooked; for though they are usually administered in this disease, they are never exhibited with this intention. The chief obstacle to their use is the state of the mucous surfaces; for if they be not in a cool and secreting state, chalybeates are repugned by them as irritants. On this account it is most advisable to select the salts of steel the least exciting, as the ferrum tartarizatum, or to qualify the chalybeates by saline refrigerants, as by uniting the carbonate of iron with small doses of the nitrate or the sulphate of potass; or, best of all, by giving the remedy in the form of some saline chalybeate water, as the Eger. We have lately been in the habit of combining the iodine with chalybeates, and we think with very considerable benefit. They appear to correct and pro-

note each other's action. This is our formula:—*R. Tr. muriat. ferri, tr. iodinii aa ʒiii. aq. puræ ʒʒ. Guttae x. ad xxx. ter die sumendæ.* The congestion of the hepatic system may also be relieved by increasing the action of the kidneys and skin; that of the former will be promoted by the alteratives already mentioned; and that of the skin will be excited by the tepid sea-water bath, by sponging the body with vinegar and water, or salt and water, by the use of the nitro-muriatic acid lotion, by warm clothing, and by exercise; and, failing this, by gentle friction of the whole surface of the body for at least half an hour daily.

Unless a free and open state of the bowels be made to concur with the preceding remedies, they will prove abortive; but violent purging by irritating medicines is equally to be avoided. A soluble state of the bowels, procured by such mild remedies as have been already mentioned, is all that is to be desired. Sometimes a course of purging by the sal polychrest or the Harrowgate salts is of service; and when a sluggish state of the colon coincides with this disease, it is absolutely necessary that this intestine should be unloaded and preserved so.

2. Except under occasional febrile symptoms from an aggravated degree of the disease, the antiphlogistic regimen is unnecessary, and it ought never to be long-continued. According to our experience a limited diet of animal food, nutritious and easy of digestion, answers best. The meals should be small, consisting chiefly of animal and farinaceous food; all vegetables and fruits ought to be avoided, or used very sparingly. Cows' milk seldom agrees well, and ought therefore to be considerably diluted; occasionally a little beef-tea or plain bouillon answers very well as a substitute for breakfast when milk is found to disagree. Wine, porter, ale, and beer are unnecessary, and therefore better avoided. In this disease fish is a very unwholesome food.

3. In ordinary cases, when the organs of nutrition are restored to a healthy state, the natural resiliency of the constitution can generally dispense with artificial assistance; but with feeble powers of body—a marked feature of the disease of which we are treating—some further help is necessary. We cannot, however, speak much in favour of internal tonics, excepting chalybeates, (which we do not view simply in the light of tonics,) and of them we have already said enough. More benefit is derived from tonics externally applied. Of these, unquestionably the most powerful is the cold sea-bath, and the most beneficial, unless it produces languor and chilliness. The shower-bath, cold ablution, exercise in the open air, in a dry free atmosphere, either by the sea-shore or in an elevated situation. The exercise should be moderate, chiefly on horseback, or, for children, on donkeys. Amusing plays, moderate and agreeable occupation of mind; gentle friction over the whole surface for half an hour every evening; and lastly, occasional change of air and change of habits.

III.—*Follicular duodenal dyspepsia.*

Synonyms.—*Hypochondriasis pituitosa*;* *Auct. Var.*; *aurigo frigida* ab obstructione, *Sauvages*; *infarctus, Kämpf*; painful affections of the intestinal canal, *Powell*.†

General character.—Symptoms of painful or difficult digestion, felt chiefly a considerable time after taking food, most frequently observed in phlegmatic habits; occasional alvine discharges of mucus in various morbid states; acute attacks of gastrodynia or jaundice sometimes intervening.

Form of disease.—In persons of a cold temperament and relaxed habit, characterized by softness and want of elasticity of fibre, dark carbonized blood, a slow circulation, a soft pulse, low animal temperature, yellowish or chlorotic, and sometimes swarthy paleness of the skin, who are also much disposed to sleep, shewing great languor, sluggishness, and apathy in their feelings, and betraying a want of decision and energy in their moral and intellectual character,—disorder of the duodenum assumes a particular form, depends upon a peculiar morbid condition, and manifests itself by certain characteristic symptoms.

The general progress of this species of dyspepsia is insidious, and can hardly be distinguished from the other forms of duodenal disease, except that the appetite is commonly much impaired, sometimes to loathing. There is great languor, lassitude, and incapacity for every exertion. The patient complains of a sense of load, distention, or pain some hours after taking food, and the digestion is accompanied with flatulence, oppression, anxiety, sometimes amounting to a feeling of suffocation. There is no remarkable loss of flesh, but the appearance of the skin is much altered; the complexion becomes bloated, loses its colour, is dull and cloudy, sometimes swarthy, frequently clammy, greasy, or waxy, as if covered with a thin film of melted wax; or the skin is sallow and somewhat jaundiced; it feels generally cold, moist, and clammy, the hands and feet particularly so. The lips and gums are generally pale; the tongue is moist, pale, and flabby, covered with a pearly white mucous coating, but seldom much loaded; sometimes there is a thick, shaggy, cottony fur. The mucous coating of the tongue often has the appearance of a false membrane, which, falling off in pieces, leaves patches quite clean, sometimes red and morbidly tender. The bowels are almost always constipated, but diarrhoea is sometimes, though rarely, observed; the stools are light-coloured, porraceous and abundant, out of all proportion to the ingesta, and having often a faint mawkish smell; occasionally they are dry and dark-coloured, more frequently fluid and dark, of a greenish or brownish black colour, and not uncommonly dark, viscid, and pitch-like. But the characteristic feature of the evacuation are considerable quantities of mucus, which are discharged in various morbid states and forms: some-

* *Fracassini*, cap. 4, p. 388.

† *Med. Transact.* vol. vi.

times it resembles transparent jelly, or is glairy like the white of an egg; frequently yellow and viscid like the yolk of an egg; sometimes it assumes the solid form, appearing in concrete masses varying in size and figure, frequently resembling small bits of tallow, wax, suet, or bits of the blanched kernel of walnuts; in other cases it appears in large shreds of a semi-transparent membrane of considerable tenacity; or large quantities of flakes mostly torn into irregular shapes, and appearing to have formed parts of an extensive adventitious membrane of no great tenacity or firmness; sometimes the membrane is passed in perfect tubes of considerable extent. Frequently it is passed in solid cylindrical forms like shreds of boiled macaroni or vermicelli, not rarely mistaken for the detritus of worms; and on some occasions considerable quantities of mucus of a purulent appearance are discharged at once, leading to the supposition that an abscess has burst internally. These discharges of mucus appear to take place periodically, and as it were critically, being in general preceded by considerable aggravation of the symptoms, whilst the recovery is attended with evacuations of quantities of mucous or glutinous substances.

In these attacks the patient is sometimes suddenly seized with acute spasmodic pain in the right hypochondrium darting through to the back, frequently accompanied with vomiting or a hard dry cough, by either of which the pain is greatly exasperated. Often there is sudden and excessive pain towards the epigastrium, returning with vomiting, in violent paroxysms. These pains are occasionally rather relieved by pressure; but the parts are frequently so sensitive that the slightest touch cannot be borne, and even during the intervals of the pain the patient complains of great tenderness and soreness in these parts. The tongue, already coated with a white fur, becomes dry, the pulse accelerated, the stools white, the urine turbid and of a dark red colour, like blood. As the pain remits, the patient is bathed in a profuse perspiration. After a day, sometimes longer, the skin becomes jaundiced, and on examining the evacuations, instead of gallstones, as he expected, the physician finds copious flakes of mucus in various forms, which are passed with considerable relief to the patient. This mucus, sometimes fluid and approaching to pus in appearance, has, in connection with the foregoing symptoms, frequently imposed the disease upon the attendants for the rupture of an abscess of the liver; but the same symptoms and the same discharge occasionally occur without jaundice or any symptom of hepatic obstruction.

The urine, in the ordinary progress of the disease, is extremely variable; in the early stage it is rather pale and abundant, occasionally crude and transparent like water, and voided in considerable quantities; but during the severity of the symptoms this secretion becomes very deficient, high-coloured, and extremely loaded, sometimes of a deep orange

colour, unless there be some obstruction of the biliary secretion, when, as has been already observed, it is of a dark blackish brown colour, like porter, or, mixed with a copious lateritious sediment, it almost resembles blood. The pulse, except during what may be called the acute attack, is always weaker than natural, generally slow and small, more rarely frequent and small, or wiry and fluttering.

The seat of the disorder may entirely escape the notice of the patient and even the observation of the physician; the chief complaint, frequently the only object of the treatment, instead of indicating any derangement of the function of digestion, may be an affection of another part of the body, some of the multifarious symptomatic diseases which originate in this disorder. Among the secondary affections which occasionally accompany this morbid state of the small intestines, (for we do not pretend to confine it strictly to the duodenum,) are, a remarkably altered state of the temper and feelings, languor, indifference to every thing, complete apathy, sometimes stupor or fatuity, sadness, great depression of spirits, obstinate melancholy, great irritability of temper, moroseness, obstinate silence and reserve. Sometimes the patient is oppressed with irresistible drowsiness during the day, and troubled with want of sleep at night, or the sleep is disturbed by dreams and incubus. The uterine functions seldom escape the influence of this disorder; menstruation is generally deranged, being either painful, irregular, or deficient, and the secretion pale-coloured: leucorrhœa is a very common attendant of the complaint in early as well as in protracted cases. Frequently the patient complains of uneasy sensations about the heart, of a sense of fluttering, of violent palpitation or syncope. The organs of respiration often suffer in consequence of this disorder; hence dyspnoea, short dry cough, frequently moist humoral cough with a grey viscid expectoration, or pain and sense of weakness of some part of the chest; in children a spurious form of croup is one of the most common symptomatic affections. The nervous system is often the chief seat of disorder, and chorea one of its most common forms; sometimes it affects the whole body, less often only one half the body, generally the right, and on some occasions only one of the extremities, very commonly the right arm. Paralysis, generally partial, affecting one, seldom more, of the limbs, is another form of secondary affection. Painful local affections are often the chief subject of complaint, rheumatic paralysis, rheumatic gout. *Erysipelas*, *erythema*, *acne*, and *impetigo*, are the most common affections of the skin which originate in this disorder.

The unfavourable progress of the disease leads to a state of general cachexy, *cachexia pituitosa*, which sometimes terminates in anasarca.

Pathology.—This species of dyspepsia, noticed by some of the ancient physicians, has been more frequently concealed under the name and description of other disorders. Oversha-

dowed by the secondary affections which originate in it, it is only to be found masked under the symptomatic forms of other diseases. But the morbid products of the mucous secretion have scarcely escaped the observation of any practical physician. Marcard* and Stoll† have particularly described them; Theden‡ and Hoffmann§ have considered them as not an unfrequent cause of sudden death; Bonnet, Morgagni, Vesalius, Brunner, and other pathologists worthy of every confidence, have discovered them in the dead subject; and the minuter researches of modern anatomy have traced them to their proper origin. But this morbid condition of body never received its due share of importance until the work of Kämpf,|| a Dutch physician, by whom it was first professedly described under the name of *infarctus*, and who must be considered to have established it as a particular disease. Though this author was in some degree guilty of the common error of most original thinkers, of overstepping and overcharging his premises,—for he said he recollected few diseases which were not originally referable to *infarctus*,—it was not so much this fault as his singular method of cure, which failed to lead to a more general reception of his opinions, which, except in Germany and Holland, have been too little attended to. In our own country, as far as we are aware, the pathological condition of this disorder has never been accurately specified, though the secondary forms of diseases under which it masks itself have been frequently described. A few interesting cases of the primary disorder have been given by Dr. G. D. Yeats,¶ but more particularly by Dr. Powell.**

It has been observed by those who have devoted much attention to morbid anatomy,†† that the mucous glands of Peyer and the follicles of Brunner do occasionally present appearances very different from that of the healthy state. Sometimes they are found unusually developed; as large as mustard-seeds; frequently they contain a whitish concrete matter, more or less friable, bearing a close resemblance to the caseous or lardaceous matter of tubercles; at other times a great number of small white bodies are found disseminated over the surface of the intestines, corresponding to the grub or *emphragma sebaceum* of the skin; for they are nothing more than the follicles filled with concrete mucus. These bodies occasionally acquire considerable size, but seldom exceed that of a pea; sometimes they are elongated, projecting in the form of little excrescences or fungous papillæ; or on the contrary, the follicles are flattened and depressed, with their orifice more or less appa-

rent, from which is thrown out a thin greyish mucus, which sometimes collects in astonishing quantities in particular parts of the intestinal canal, or, spreading itself in every direction, forms a thick mucous coat over a considerable part of the surface of the intestine, which on the first view might easily be mistaken for the mucous membrane itself in a white and healthy state; sometimes it is a tenacious mucus of a dark brown colour; or instead of this greyish semi-transparent semifluid mucus, a concrete matter, equally secreted by the follicles, may spread itself in the form of a membrane, more or less dense, over the surface of the intestinal canal; or instead of being spread on the surface, this concrete matter may form solid masses, as occurred to the celebrated Justin Lipsius, who, though treated by his friend and colleague Heurnius, suffered for a long time from this complaint, and was not relieved till he had voided a viscid mass of the colour and form of the intestines.

It was the doctrine of the school of pathology just disappearing, to consider all these morbid appearances as the result of inflammation of the mucous surfaces. Dr. Parry observes that the appearance of the fibrous and curdled stools of children, and the consistent concrete membranes taking on the tubular form of the intestines in adults, which are often evacuated from the bowels in slight inflammatory affections of the mucous membrane of the colon and rectum, so often mistaken for worms, consist rather of coagulated albumen than of concrete mucus; but there does not appear any just reason for this opinion. We have observed these without the remotest sign of inflammation; nor did Dr. Powell observe any, but on the contrary states that the most remarkable circumstance in the history of his cases was the production of an effect usually ascribed to inflammatory action without its previous existence.

There will be little difficulty in understanding how all the various symptoms and sufferings described as originating in this morbid condition of the mucous follicles may be consequences of it, if we allow a due importance to these organs in preserving a healthy action of the membrane of which they constitute so essential a part. On comparing the various morbid appearances presented by a disordered state of the follicles, we may remark that they divide themselves into two classes; one in which the secretion is suppressed or retained, and another in which it is excessive or overflows, to each of which opposite states a more precise observation will in all probability ascribe its appropriate symptoms. In the mean time it may be easy to conjecture how the mucous membrane, not defended by its appropriate secretion, may acquire a preternatural sensibility and irritability, which, not only disturbing the function of digestion, and giving rise to most painful affections of the intestinal canal, but rousing the actions of its sympathetic organs, may induce any of the disorders which we have noticed; and how, on the other hand, the membranes, sheathed and muffled by the morbid envelope, and thus deprived of their sensibility,

will induce disorder and excite sympathies of another character, and will also sometimes become mechanical causes of irritation and obstruction. The inconvenience of a dirty skin, as a writer on this subject observes, is felt, because its obstructed pores prevent the transmission of that insensible perspiration which is essential to health; languor, sickness, headache, and other inconveniences originate precisely in the same manner, from filthy intestines. And we know that the mucous membrane, either by sympathy or association, sometimes degenerates into a state relatively similar to that of the teguments of the surface of the body, which sometimes become hard, harsh, and rough; or glossy, smooth, and shining, like parchment; pale, weak, and withered, or covered with large thick scales of cuticle adhering to its surface, thus losing all its permeability; or, on the other hand, besmeared with an excess of sebaceous secretion covering the skin with an oily, greasy, or waxy coating. When both these secreting surfaces, the skin and the mucous membranes, cease at the same time to perform their offices, it is not difficult to understand how the fluids become disordered, how nutrition becomes impeded, and how the most inveterate forms of cachectic complaints ensue.

Our pathology of this complaint receives considerable illustration and confirmation from considering its causes. It has been observed most frequently in females and children, in whom the mucous follicles are most developed; it prevails most in cold humid seasons, in cold humid climates, and therefore, prepared by the influence of winter, it often declares itself in early spring, and on the return of cold in autumn. Sedentary employment in confined and impure air, with neglect of personal cleanliness, are the circumstances most powerful in producing it; to which may be added unwholesome food. When the predisposing causes have been in operation, it is generally immediately excited by colds, errors of diet, drastic purgatives, fatigue, watching, anxiety, alarm, and bodily accidents. Constipation of the bowels, while it is a consequence, is also one of the exciting causes of this disease.

Method of treatment.—The indications for directing us in the cure of this disease, are, 1, to render the function of digestion easy of performance by a proper selection of food, by preserving an open state of the bowels, and by proper exercise; and, 2, by endeavouring to correct the morbid condition of the follicles, which constitutes the proximate cause of the disease.

1. Having already so fully and so frequently considered the means of fulfilling the first indication, it will be unnecessary again to recur to that subject; we shall, therefore, content ourselves with referring to the treatment of *follicular gastric dyspepsia*, and shall for the present confine our observations to the means of fulfilling the second indication.

2. Some medicines appear to exert a particular influence upon the functions of the mucous follicles. According to our experience they consist of purgatives, especially rhubarb,

senna, scammony, and aloes, of sulphurous and some neutral salts, as sal polychrest, muriate of soda, of alkalies, mercurials, chalybeates, of iodine, colchicum, gum ammoniacum, and ipecacuanha. Amongst several means capable of effecting the same object, it is a received principle of physic to select those whose operations are best known and most under controul, having recourse to others only when their use cannot be dispensed with. Accordingly, some of the purgatives above enumerated, either alone or in combination, form the proper remedy of this complaint in milder cases; and where no signs are present indicating an inflammatory or excited state of the mucous membranes, rhubarb, with sal polychrest and a small proportion of ginger, the pulvis scammoniae compos., the infusion of senna; in cold habits, the vinum aloes, the decoct. aloes comp., and the baume de vie, are convenient combinations. Dr. Powell found, in his cases, that the infus. sennæ with the infus. gentian. comp., and from x to xx minims of liquor potassæ, repeated so as to produce four or more stools in the twenty-four hours, discharged the flakes of mucus better than saline aperients, and more efficaciously than mercurials. Where there were general torpor or coldness of the system with much pale urine, and dark stools with much mucus, Dr. Yeats observed very excellent effects from taking one drachm of the vinum aloes with xv minims of liquor potassæ in a little infusion of chamomile every morning. It is not enough that these medicines be taken in isolated doses. To give them effect, they must be steadily persevered in for some time. But their effects must be watched. If they cause irritation, heat, thirst, or much griping, they are not indicated, and may induce the very state we are seeking to remove. The largest fistulous membranes that we ever recollect to have seen discharged by stool, we observed in two ladies who were in the habit of using the electuary of senna every day as an aperient.

The operation of purgatives is rendered much more efficient when the bowels are prepared for their action by one or two small doses of alteratives. Of these the most certain and most manageable are mercurials, and we believe calomel to be the best form of this medicine. One, two, or three grain doses are generally sufficient, and, according to the state of the patient's stomach, it may be combined with the pil. galban. comp., the pil. scillæ comp., with a little prepared chalk if there be a disposition to diarrhœa, or with a minute quantity of opium or opiate confection.

Chalybeates, though in a less degree, possess the same alterative power over the follicles as mercurials, and united with their tonic properties afford a means of cure applicable to another combination of circumstances: as for instance, when there exists a general torpor and coldness of the system, with much pale urine; when the patient is thin, pale, and weak, with a withered look, a peculiar dry state of the skin, and a small weak pulse, the appetite variable and capricious, the bowels

slow, though easily regulated, and the evacuations always of a remarkably dark colour, like mahogany, or almost black; or when the patient is pale, bloated, and chlorotic; in all such cases chalybeates are very useful remedies. The most suitable preparations are the sulph. ferri combined with pulv. aloes; the ferum tartarizatum or ammoniatum with rhubarb, or the carbonas ferri with rhubarb and soda. It has been observed in these cases, contrary to what happens in general, that chalybeates, instead of rendering the fæces darker, restore them to their natural colour, an observation which is in accordance with the experience of Nehr and Heidler, of the action of the mineral water of Marienbad.

Kämpf's method consisted in injecting frequent small enemata of strong decoctions of plants which he supposed to be endowed with resolving powers, as *turaxacum*, *saponaria*, *melilotus*, and such-like; these he allowed to be absorbed from the intestines.

It is always desirable, as far as the case admits, to combine some tonic with the corrective treatment, and, as soon as the evacuations have assumed a healthy appearance, it may always be attempted. Chalybeates, as already observed, answer this purpose best; but when they are not admissible, or after their use, tar-water, lime-water, infusion of cascarrilla, nitric or nitro-muriatic, or muriatic acids, are very useful remedies.

It is unnecessary to observe that this direct method of cure must be assisted by all those means which tend to the improvement of the general health, and which at the same time correct and avoid those habits which form the predisposing causes of the disease. Amongst these the state of the skin deserves particular attention. The warm sea-water bath, the cold sea-bath, the cold shower-bath, cold sponging with vinegar and water, or salt and water, friction with a flannel glove, warm clothing, preserving the feet dry and warm, will be found most useful auxiliaries.

But a remedy superior to any or even all of these, we have found in mineral waters, by which every intention of the medical treatment, corrective as well as tonic, we have seen more efficiently, more fully, and more surely accomplished than by any other combination of remedies. Some of the most surprising cures effected by mineral waters have been chiefly in affections of this nature, as has been observed at Carlsbad by Becher, at Marienbad by Heidler, in the waters of the Pyrenees by Bordeu, at Pymont by Marcand, and also at Eger and Harrowgate.

III. COLONIC DYSPEPSIA.

The functions of the large intestines being chiefly disordered.

Alvine excretion forms so important a part of the function of digestion, that, in common language, the term indigestion is exclusively appropriated to the disorder of that function; and if it be impeded, interrupted, or otherwise deranged, it is rare that its other processes continue to be healthily performed. There

may be some exceptions to this, as in the extreme cases mentioned by Heberden, where one person was in the habit of having his bowels relieved only once every month, and another person twelve times every day, yet both with the enjoyment of perfect health; and in all persons, what is called the regularity of the bowels admits a certain latitude; but in ordinary circumstances the right performance of excretion is so essential to the health of the whole function of digestion, than any serious or long-continued irregularity of the bowels invariably leads to its disorder. We cannot, therefore, be said to have exceeded the limits of our definition in considering disorders of the functions of the large intestines as constituting species of dyspepsia.

The large intestines are very frequently, indeed most frequently, the part of the apparatus of digestion of which the functions are the first disordered; and the symptoms of their disorder often present the first perceptible link of the chain of the disorder of the whole apparatus; and though ultimately their disorder necessarily involves the whole apparatus, their derangement may so entirely predominate, that the healthy or unhealthy state of the other processes follows as a mere consequence of the state of the large intestines.

The disordered functions of the large intestines, considered only in reference to the part which they perform in digestion, without regard to the more positive diseases of which they may be the seat, are of themselves a source of great discomfort to the patient; but they deserve most consideration as being the medium through which the greater number of the disorders of the function of digestion become established, not only directly, by the impediment which they present to the function of the stomach and small intestines, but indirectly, by the stomach being made the recipient of the medicines which are necessary for their relief. The disordered function of the large intestines may, therefore, be considered as the means by which most of the noxious causes which disturb the healthy function of digestion produce their effect, and the principal secondary cause by which they extend their mischievous consequences.

The disordered functions of the large intestines afford almost the first symptoms of the derangements of the stomach and small intestines, which attract the attention of the patient, and have not seldom been improperly treated as a dyspeptic state of the stomach itself. This, as Dr. G. D. Yeats very justly observes, is not remarkable, it being recollected that the great arch of the colon lies close upon the stomach, whence a swelling or puffiness in the one may easily, without due care, be attributed to the other.

As long as the disorders of the large intestines continue to predominate over the disorders of the other parts concerned in the function of digestion, they have their own symptoms, and demand their own method of cure. When they have induced the disorder of the whole function, it is always important to know where

the error originated; and as their disorders may be mistaken for those of other organs, it is necessary that a distinction should be made between them. Under every consideration, as the disorders of the functions of the large intestines admit of being ascertained, so they deserve being made a subject of special attention.
